Truncated Wings—The normal wings of *Drosophila* are longer than the abdomen, extending for about one third their length beyond the end of the body The wings have a rather pointed end In the seventh generation of the beaded wing stock a fly appeared with the end of the wings cut off nearly squarely, and indented at the end or somewhat scalloped Bred to sister flies there were produced in the next generation twenty-one flies with truncated wings to 230 with normal wings. In the next generation some of these truncated winged flies produced nearly 50 per cent of flies with truncated wings. It has proved difficult to pass beyond this point, although certain of the later cultures have produced over 90 per cent. of truncated winged flies This high average has not, however, been maintained in the next generation There are indications, nevertheless, that the inheritance may be raised even to this high standard Two main points of interest have appeared in the breeding of this modification First, the condition is confined almost exclusively to the female line A comparison of many cultures shows that the offspring of truncated parents consist of almost equal numbers of males and females with normal wings, while the truncated winged forms are, as stated, confined almost exclusively to the females The deficiency of males in the entire culture is due, therefore, to the absence of males with truncated wings Yet such males appear in small numbers, and especially in cultures in which truncated males are the fathers of the next generation

Secondly, by selecting the shortest-winged individuals in each generation the wings have been reduced in some cases until they are not longer than the abdomen, and in a few cases they were even much shorter than the abdomen, and are not superficially different in this respect from the type to be next described, although in their inheritance they follow an entirely different procedure. The character can not be said to be sex-limited to the female in the conventional sense When a female with truncated wings was bred to a normal wild male all of the offspring in the first generation had long wings These inbred produced in the second generation 1,826 normal flies to 36 truncated individuals, males and females When a truncated male was bred to a normal wild female all the flies in the first generation were normal, and in the second generation, when these were inbred, there were produced 1,408 normals to 14 truncated males and females These facts indicate that this condition is not connected with sex-limited inheritance, although other wing modifications, as will be shown, are intimately connected with sex transmission It should be added that normal winged flies of this modified stock throw a high, though variable, percentage of flies with truncated wings

Rudimentary Wings—In the second generation of the beaded winged flies a male ap-

peared with wings shorter than the abdomen. The square, short wings were broad and often blistered; in individuals obtained later their ends were crenated at times as though incompletely unfolded, but at other times the ends were quite even. This fly, bred to his sisters, reproduced the same condition in a few of his male offspring, and in closely related stock a few males of this kind appeared in successive generations. By repeated intercrossing a large number of these males have been produced and some females. It is important to note that although I have paired numbers of these males and females together I have obtained offspring in only a very few cases and these were all normal flies. Inbred these normal flies have produced 964 normal males and females, 6 short winged males and 2 females. Whether the original short winged females were virgins may appear doubtful from these facts. On the other hand the males and females with rudimentary wings are fertile, both with wild flies and with the mutations to be next described. The frequent failure to obtain fertile eggs from pairs of flies with rudimentary wings may seem therefore to indicate that this combination is generally sterile, but whether because the eggs are not fertilized or being fertilized do not develop is uncertain. This point is being further investigated. The extraordinary deficiency of individuals of this class in the second filial generation (see below), may be due to the same causes that account for the deficiency when inbred. Similar deficiencies, though not so extreme (see the second generation of white-red eyed and black-yellow crosses), run through nearly all of the results with my new races.

If a male with rudimentary wings is bred to normal females of *the original stock* all of the offspring have long wings. These inbred produce variable percentages of long and rudimentary wings. A partial census of the results gave 5,850 normal wings to 83 males with rudimentary wings. No intermediate types appeared. Later several males with rudimentary wings were bred to a new *wild stock*. The offspring had long wings. These flies inbred produced in the next generation 8,459 normals, males and females, and only 32 males with rudimentary wings. The experiments show that the condition of rudimentary wings is sex-limited. By suitable combinations this sex-limited character has been combined with another sex-limited character, viz., white eyes. The theoretical questions involved in such a combination have been discussed elsewhere.[6]

Miniature Wings.—In the seventh generation of the beaded wing stock a fly appeared with wings like the normal in form, but extending no further than the end of the abdomen. Flies with wings of this kind are much more viable than those with rudimentary wings. Pure cultures of thousands of individuals are now on hand. The character also shows itself to be sex-limited. Many combinations between these flies and those with other modifications have been made. Only a few of these can be now mentioned. Miniature wings have been combined with the white eyes, also a sex-limited character.

If a male with miniature wings is crossed with a wild female all of the offspring have long wings. These inbred have produced 409 flies with normal wings, males and females, and 178 *males* with miniature wings. No females with miniature wings appeared in the second generation. Miniature wings are, therefore, sex-limited in inheritance. The reciprocal cross, viz., females with miniature wings by wild males, gave in the first generation 50 females with normal wings and 51 males with miniature wings. Evidently the male-producing sperm of the wild fly does not carry the character essential for the *formation* of long wings. This same spermatozoon also lacks, as I have tried to show, one of the factors essential for the formation of red eyes, likewise a sex-limited character. The F_1 flies, inbred, produced 785 normal males and females (in approximately equal numbers) and 827 flies with miniature wings, of which 430 were females and 397 were males. This result gives the expectation for this combination

[6] *Proc. Soc. Experimental Biology and Medicine*, Vol. 8, October, 1910, and *American Naturalist*, February, 1911.

It will be noted that the flies with miniature wings are even more numerous in this generation than the normal flies Their chances for development are therefore at least equal

Balloon Wings—Occasionally flies have appeared, especially in the truncated winged stock, with each wing swollen up into a balloon or bladder filled with fluid When these become dry the walls collapse and form flat plates that are carried at right angles to the body Some of these flies have been isolated and have produced practically pure stock with the character present in all of the individuals, and this condition has been carried through two generations The flies are exceedingly active and look like small X's running about in the bottles They can not of course fly They seem to be very sterile and produce only a few offspring, but nevertheless I have more than a thousand of these flies alive at present

Albino Flies—Several times flies have appeared that failed to develop black pigment in the body The eyes were red, *i e*, unmodified by the lack of body pigment One of the albinos had white eyes, it is true, but it arose in white-eyed stock, so that the colorless eye bore no relation to the absence of pigment in the body The wings of these albinos were almost white with a faint brownish edge The hairs of the body were brown instead of black Although some of these flies lived for nearly a week they left no offspring When the normal fly emerges it lacks pigment except in the eyes

Melanistic Flies—In some of the crosses between wild flies and those with miniature wings there have appeared in the second generation some flies, males and females, with black wings The veins of the wings are broad and conspicuous Pure stock of these flies was easily, and at once produced The dark color is not confined to the wings, but the entire body is black The type is clearly a melanistic variation of *Drosophila* Crossed with wild stock the flies of the first generation are intermediate in color between the black and the normal type The color does not seem to be sex-limited in relation to the normal, so far as the experiments have been carried.

Yellow Wings—A male appeared in the black-winged stock with golden yellow wings In fact the entire fly is conspicuously yellow and makes a striking contrast with his dark companions He was bred to his black sisters and gave only black flies in the first generation These were inbred and have produced 233 black females, 127 black males and 76 golden winged males Evidently the color is sex limited in relation to the melanic type from which it arose The same or a similar mutation, has appeared again in a stock not related to the first except in so far as both came originally from flies with miniature wings As yet only males have appeared These have given in the first generation (when crossed to their normally colored sisters) normal flies

Wingless Flies—Occasionally flies appear without wings, but this character is not inherited as a rule, and is due to some difficulty in unfolding the primordia of the wings But in some of the stock of truncated wings I have obtained a considerable number of flies with tiny scales in place of wings In one culture there appeared 11 flies with scales, instead of wings, amongst 125 winged flies Although this stock is very sterile it seems not improbable that, in time, a wingless fly can be produced

COLUMBIA UNIVERSITY

THE NATIONAL CONFERENCE COMMITTEE ON STANDARDS OF COLLEGES AND SECONDARY SCHOOLS

THE fifth annual meeting of the National Conference Committee on Standards of Colleges and Secondary Schools was held at the rooms of the Carnegie Foundation for the Advancement of Teaching, 576 Fifth Avenue, New York, N Y, on Saturday, January 28, 1911

All the organizations which send delegates to the conferences of this committee were represented, those in attendance being as follows

President George E MacLean, The State University of Iowa, representing the National Association of State Universities

Headmaster Wilson Farrand, Newark Academy, representing the College Entrance Examination Board

Professor Nathaniel F. Davis, Brown University, representing the New England College Entrance Certificate Board.

Dean Herman V. Ames, The University of Pennsylvania, representing the Association of Colleges and Preparatory Schools of the Middle States and Maryland.

Principal Frederick L. Bliss, The University School of Detroit, representing the North Central Association of Colleges and Secondary Schools.

Chancellor James H. Kirkland, Vanderbilt University, representing the Association of Colleges and Preparatory Schools of the Southern States.

President Henry S. Pritchett, representing the Carnegie Foundation for the Advancement of Teaching.

Dr. Kendric C. Babcock, as substitute for Dr. Elmer E. Brown, the United States Commissioner of Education.

Dean Frederick C. Ferry, Williams College, representing the New England Association of Colleges and Preparatory Schools.

In its desire to help in the establishment of a uniform and convenient terminology, the committee had requested a sub-committee to prepare for this meeting a report with regard to the use of the terms "hour," "count," "unit," "period," "exercise," "point," etc., in secondary schools and colleges. Mr. Farrand, chairman of the sub-committee, reported the results of the investigation which had been made and embodied these results in the following resolution, which was unanimously adopted.

Resolved, that this committee recommends, as a matter of convenience and to secure uniformity:

1. That the term *unit* be used only as a measure of work done in secondary schools, and that the term *period* be used to denote a recitation (or equivalent exercise) in a secondary school.

2. That the term *hour* be restricted to use in measuring college work, and that the term *exercise* be used to denote a recitation, lecture or laboratory period in a college.

3. That *unit* be used as defined by this committee, the Carnegie Foundation, and the College Entrance Examination Board, and that *hour* be used preferably in the sense of year hour.

4. That the use of other terms such as *count*, *point*, *credit*, etc., in any of these senses be discontinued.

The sub-committee had been requested also to consider and report on the desirability of agreeing on the precise use of the terms "programs of study," "curriculum" and "course of study." Mr. Farrand reported that this question had been carefully considered by his committee in the light of the published resolutions of the National Association of State Universities and of the Association of American Universities and such further information as could be procured. While conscious of the desirability of uniformity in the use of these terms, the sub-committee felt that it was unwise to take any action until some common usage should have become established in many institutions.

Following a discussion of the question of a combination of the examination and the certification methods of admission to college, Dean Ferry presented the following resolution which was unanimously adopted:

Resolved, that this committee endorses the movement of various colleges in the direction of attaching weight to the school record of each candidate in connection with his entrance examination, and recommends to the colleges that such records be regularly used as an aid in determining the candidate's fitness for admission to college.

The question of the proper use of the term "honorable dismissal" was considered at some length and the secretary was requested to obtain further information on the subject and to report at the next meeting.

Various questions proposed for discussion were laid on the table and the sub-committee, consisting of Headmaster Farrand, chairman, Principal Bliss, President Pritchett and Dean Ferry, was continued with a request that it report again at the next meeting.

The officers of the past year were reelected as follows:

President—President George E. MacLean.

Vice-president—Headmaster Wilson Farrand.

Secretary-treasurer—Dean Frederick C. Ferry.

The full report of the proceedings of the conference will be printed for distribution to the members of the associations which are represented in the committee.

FREDERICK C. FERRY,
Secretary-treasurer

ANTHROPOLOGY AT THE PROVIDENCE MEETING

THE annual meeting of the American Anthropological Association was held in Providence, R. I., December 28–30, 1910, in affiliation with the American Folk-Lore Society. The sessions were held in Manning Hall, Brown University. In the absence of President William H. Holmes, Professor Roland B. Dixon presided. The attendance was good and a number of important papers

were presented On the morning of December 29 there was a joint meeting of the association and the Archæological Institute of America in Union Auditorium, at which Miss Alice C Fletcher presided

ADDRESSES AND PAPERS

In the absence of President Henry M Belden, of the American Folk Lore Society, his address was read by Dr Charles Peabody Some of the most important papers read at the joint meeting are represented in this report by abstracts These are

Recent Progress in the Study of South American Indian Languages Professor ALEXANDER F CHAMBERLAIN

The author pointed out the regions of the South American continent to which, during the last five years, scientific research had been particularly active the Colombia-Venezuela borderland, northwestern Brazil, Ecuador Peru Bolivia, southern Brazil, etc Noteworthy are the investigations of Tavera Acosta, Koch Grünberg, Rivet and Beuchat, Farabee, E Nordenskiöld, von Ihering, et al To Tavera Acosta we owe rather extensive vocabularies of the Guahiban, Piaroan, Puinavian, Salivan and Yaruran stocks, all of which hitherto have been rather scantily represented by linguistic material Koch Grünberg, as a result of his sojourns in northwestern Brazil, has shown the Makuan to be an independent stock and added much to the linguistic material in print and in manuscripts concerning the Arawakan, Cariban, Betoyan, Miranhan and Uitotan stocks Rivet and Beuchat studying the extensive linguistic material obtained by the former of these authors (they are now working jointly), have thrown much light on the ethnologic problems of the Ecuador Peruvian border land, delimiting the areas of the Jivaran (Rivet has shown Brinton's "Jivaro" to be really Jebero and, therefore, Laman, or as he terms this stock, Cahuapana), Zaparan, Laman (Cahuapana), etc Rivet believes that the Jivaran has marked Arawakan affinities, and his later studies claim to attach some of the minor stocks of southern Colombia to the Chibchan Dr Farabee's investigations have resulted in the accumulation of much lexical and grammatical material concerning the Arawakan peoples of Peru, also vocabularies, etc, from tribes of Panoan, Uitotan, Jivaran and other stocks The thorough study of this valuable material will add not a little to our knowledge of the linguistics of the Peruvian area E Nordenskiöld has devoted some attention to the little-known tribes of eastern Bolivia, and we may expect other data of value from him in the near future To von Ihering belongs the credit of having first established beyond a doubt the independent character of the Chavantean stock Here should be mentioned also the researches of Barrett recently initiated into the language of the Cayapa, etc, of the Barbacoan stock Of works of a more or less bibliographical character the most important are Lenz's monograph on the Indian elements in Chilean Spanish, Schuller's contributions to Araucanian bibliography, etc, and Mitre's "Catalogo," with its introduction by Torres

Recent Literature on the South American "Amazons" Professor ALEXANDER F CHAMBERLAIN

The author résuméd and discussed the monographs of Lasch, Friederici and Rothery, all published during the year 1910 Of these the study of Friederici seems the most satisfactory, the book of Rothery, however, the most ambitious, treating the ancient and modern Amazons all over the globe Dr Friederici rejects the view of Ehrenreich and Lasch of a unitary origin of the Amazon legends among the northern Caribs, with extension thence over all northern South America Both in content and origin the Amazon legends differ notably from each other in several cases, and they are of multiple provenance In some there is evidence of modification and contamination through European sources Among the causes of the origins of South American "Amazon" legends he enumerates the following

1 The notably war like character of women in many primitive American communities

2 The peculiar power or influential position of women (due to economic, religious, hereditary or other social reasons) in a few tribes, which made a great impression upon the mass of the surrounding communities

3 Rumors of the barbaric splendors of the empire of the Incas, which had penetrated the wilderness to the east

4 Reports of certain unusual sexual relations of Indian women, etc

5 Tales of "Amazons" due to native reports misunderstood by the Spaniards, or from such tales intentionally spread by the latter

Amazon legends are reported from the West Indies (Ramon Pane records a characteristic one), from Yucatan and from Mexico The Mexican legends, Dr Friederici thinks, are "the least founded of all, ethnologically or mythologically"

(p. 23). Ill founded likewise are the legends from California and the northwest Pacific coast. Incidentally, Friederici points out that the account attributed generally to Orellana belongs really to Carvajal, and that the river of the "Amazons" received its name from the valor of the Indian women met with by the Spanish explorers.

The Uran: A New South American Linguistic Stock: Professor ALEXANDER F. CHAMBERLAIN.

In 1891 Brinton recognized[1] in the region of Lake Titicaca a Puquina linguistic stock, observing at the same time that "the Puquinas are also known under the names of Urus or Uros, Hunos and Ochozomas." In this he was followed by R. de la Grasserie, in his "Langue Puquina" (1896), and others since then. In 1895–96, Dr. Max Uhle collected from the Urus of Iruitu, etc.,[2] a vocabulary of some 600 words, many sentences, etc., all of which material seems to be as yet unpublished. In 1897 J. T. Polo visited the Urus of Nazacara and obtained a vocabulary of some 150 words, 33 phrases, etc. This material did not appear in print till 1901[3] and constitutes the published linguistic data concerning the Uran stock. The author presented in English alphabetic arrangement a considerable portion of Polo's vocabulary, with grammatical notes, etc. Polo's work seems to have been practically unknown to ethnologists, Roman[4] being about the only one to recognize its importance and to see that the Uran and Puquinan must be unrelated. Careful examination by the author of this paper of the Uran linguistic material and comparison with Atacameñan, Puquinan, etc., prove beyond a doubt that the language of the Urus of Bolivia constitutes an independent family of speech. The few descendants of the ancient Urus, and the fewer still who keep their mother tongue (many having adopted Aymará) are to be found scattered along the Rio Desaguadero between Lake Titicaca and Lake Aullagas or Poopo, particularly at Iruitu, Sojapata, Ancoaqui, Ahuallamaya, Nazacara, etc. In the past they evidently occupied a much wider area between these two lakes.

It is worth noting that the confusion of the Urus with the Puquinas began with Hervas, Garcilasso de la Vega, *e. g.*, among the older authorities distinctly separating the two languages. This separation of the Uran and Puquinan stocks clears up somewhat the linguistic difficulties of this region of South America, but leaves the Puquinas, their origin and the extent of their language area, perhaps as much of a problem as ever.

The Age-societies of the Plains Indians: Dr. R. H. LOWIE.

Age societies have been ascribed by ethnologists to a large number of Plains tribes. A sharp definition of the age factor results in limiting the number to the Blackfoot, Village tribes, Arapaho and Gros Ventre (Atsina). The question arises whether in these cases the age factor is a basic or derivative feature. Investigation proves that the age element is a subordinate feature, the collective purchase of ceremonial regalia, songs and dances being apparently the dominant motive.

Some Aspects of New Jersey Archeology: Dr. CHARLES PEABODY.

Slides were shown illustrating the three celebrated strata at Trenton, N. J., on the glacial terrace above the Delaware River, viz., the black soil, the yellow loam, probably of immediate post-glacial deposition and the true "Trenton" gravels underlying the yellow soil.

Attention was called to certain discoveries made during the season's work of 1910 by Mr. Ernest Volk, who has spent large portions of the last twenty-two years in exploration and observation of the region.

1. *The Bison Bone*.—On June 22, 1910, in the sand pit of Mr. Ahrendt on the terrace was found an artificial pit, the cross section was: at the top six inches of black soil, under this one foot of yellow loam, and under this a red clay band one inch thick. In the pit were found the femur of a bison and accompanying it fine particles of charcoal. In the red band on one side of the pit lay a chipped water-worn pebble of argillite, and in the same red band to the left, a water-worn pebble of argillite, not chipped.

2. *The Artificial Pit*.—On August 23, 1910, in the sand pit of Mr. Ahrendt, on the terrace was found another artificial pit, the cross section: at the top, six inches of black soil, under this yellow loam (with thin red bands) three feet six inches thick, and under this, overlying the pit, three or four inches of brown sand and charcoal. Nothing but charcoal of human provenance was found in the pit.

3. *The Natural Pit*.—In the same sand pit, seven feet down under a somewhat similar series

of natural strata, was a pit made by ice, probably, or by some other natural agency The importance of commenting on these three pits together consists in drawing attention to the similarity of geological and climatological conditions under which the pits were formed Light is shed on the question of the contemporaneity of man with the post glacial conditions which permitted the deposition of the yellow drift and the formation of the series of so called "ice pits", the bison is added to the list of animals which lived as contemporaries with man at this epoch A photograph taken by Mr Volk was shown giving the negative in yellow loam of a large boulder which had fallen out, the similarity of forces which were sufficient to transport such boulders during the formation of the yellow drift with those forces undoubtedly of glacial origin that deposited great boulders in the gravels lower down was insisted upon Reference was made to the continuity, accuracy and fidelity of Mr Volk's work

The Historical Value of the Books of Chilan Balam Mr SYLVANUS GRISWOLD MORLEY

The recovery of aboriginal history in America is exceedingly difficult because of the absence of original sources from which it may be constructed To this general condition, however, the Mayas of Yucatan offer a striking exception Centuries before the Spanish conquest this intelligent people had developed an accurate chronology and a system of hieroglyphic writing by means of which they recorded their annals

These aboriginal records were destroyed at the time of the Spanish conquest, but in the century that followed (1550–1650) there grew up a body of native writings called "The Books of Chilan Balam" in which were embodied much of the aboriginal history of this country The case for and against these chronicles as reliable sources for the reconstruction of Maya history may be summed up as follows

A *Unfavorable*

1 Breaks in the sequence of the katuns, the unit of enumeration used in the chronicles for counting time

2 Certain disagreements, usually of time, in the statement of facts

B *Favorable*

1 Very general agreement throughout

2 Early date at which the chronicles were compiled (1550–1650), when the ancient history had not yet been forgotten

3 Authorship by natives, many of whom had grown to manhood before the Spanish conquest, and who had had, therefore, opportunities for learning their ancient history at first hand, before European invasion and acculturation

4 Many corroboratory passages in the early Spanish writers

There are two important conditions, however, which will explain, in part at least, the discrepancies in the chronicles, which have been noted above under A

1 The original manuscripts have never been studied and compared, and the present translation was made from hand copies only, a condition pregnant with possibilities for error

2 The translation itself is not always accurate and indeed in several instances has been shown to be misleading and incorrect

Recent Archeological Investigations in northern Guatemala DR ALFRED M TOZZER

The area occupied by the remains of the Maya civilization may be roughly divided into various provinces distinguished from each other by chronological considerations as well as by those dealing with assemblage, construction, the manner and method of decoration and others

The area treated in detail is that which includes the northeastern part of the Department of Peten, Guatemala Tikal is the first city of importance in this region To the east is Nakum, first made known to the scientific world by Count de Périgny in 1908, and Naranjo, explored by Mr Maler In addition to these ancient sites the Peabody Museum Expedition of 1909–10 reports the new ruins to the north of Naranjo and Nakum of La Honradez, Porvenir, Azucar, Seibal 2d, and Holmul in Guatemala and those of Kotšikitam in British Honduras

These ruins are all characterized by the presence of one large court or plaza around which in most cases the greater number of stelæ and altars are placed The plan in each case shows a system of oriented courts all connected with one another with very few detached buildings

From a study of the dates now available it will be seen that this region occupies the first position in point of time in all the ruins of the Maya area It is not possible to show at the present stage of the study of the archeology of this section that the Tikal territory was the center from which spread the influence responsible for the cultures of Copan and Palenque From the evidently later character of certain of the stelæ at Tikal, it may be reasoned that not only was this region a center, which began very early in the

life of the Maya civilization, but that it continued to hold its important position until well toward the end of the time, when the southern Maya culture resigned its place of preeminence to that part of the Maya people living far to the northward

The results of the investigations of the Peabody Museum Expedition of 1909–10 will appear in the *Memoirs* of the museum

Cretan Anthropometry Professor CHARLES H HAWES

Since Professor Boyd Dawkins and Dr Duckworth concluded that the ancient Cretans belonged to the long headed dark short Mediterranean race, the examination of additional ancient skulls and measurements of living Cretans made by me have gone far to confirm this conclusion, and to show that the *average* modern Cretan is a modification of this type and has a broader head than his ancestor

Nevertheless, the facts here set forth demonstrate that the ancient Cretans or Minoans with their characteristic long head are still represented in the more inaccessible regions, and that the broadening element is due to the presence of brachycephals who are mainly confined to the plains and coasts Further, the facts are interpreted to indicate that the broad heads are descendants of aliens, and in the main to prehistoric immigrants

The data for Minoan skulls is obtained from 118 crania, of which I use here 78 male skulls (c 2000 B C), leaving out those of the Late Minoan period, during which there is both archeological and anthropological evidence of an alien immigration These 78 skulls yield an average cranial index of 74 0, and the long heads are to the broad heads as 5 to 1

The data for modern Cretans is large, amounting to over 60,000 measurements and observations, and for this reason comparisons are at present confined to the cephalic index Adding 199 Cretans measured by Dr Duckworth to those measured in my expeditions of 1905 and 1909, we have a total of 3,183 But from these have been deducted foreigners, women and children and even Mussulman Cretans, leaving 2,290 modern Cretans as the basis for the following comparisons These yield an average cephalic index of 79 0 to be compared with 76 0 (*i e*, 74 0, the cranial index, plus 2 0, allowance for the cephalic) The average modern Cretan is therefore mesaticephalic, midway between his ancestor, the ancient Cretan, and his neighbor, the modern Greek (c 82 3), and the long heads are to the broad heads in the proportion of 5 to 4 The difference is appreciable and impels us to ask, do the descendants of the ancient Cretans, with a cephalic index of 76 0, exist in Crete to day? If so, it is reasonable to suppose that the invading aliens have driven the natives up into the hills, and there we find them Present in the plains, they predominate in the mountains In the mountain plain of Lasithi (2,700 ft) the average cephalic index is 76 5, with a proportion of 9 dolichocephals to 1 brachycephal On the northern slopes of Mount Ida the cephalic index is 76 5 On the northern slopes of the White Mountains, in the west, in one village, 65 men averaged 76 9 compared with 79 9 in the plains immediately below In the Messara Mountains of the center, the average was 76 9 in contrast to 80 9 in the plains Twenty eight skulls of revolutionists of 1821 and 1866 chosen at random from the mausoleum of a mountain monastery, yielded a *cranial* index of 74 2 and a ratio of 4¼ long heads to 1 broad head In the less accessible mountain regions are thus to be found modern Cretans of similar cephalic index and ratio of dolichocephals to brachycephals to those of Minoan Crete

How then has the *average* cephalic index risen in 4,000 years from 76 to 79? I have already suggested that this change is due to the presence of the descendants of prehistoric immigrants Reviewing historic invasions, it is possible to dispense with both Turkish and Venetian somatological influence Mussulmans have been rigidly excluded from these records and the Venetians, I have shown by a careful comparison of the Venetian named Cretans with the rest, possess exactly the same average cephalic index, thus evincing a breeding out in the course of nine generations of the infusion of Venetian blood that Crete received This leaves us with the prehistoric invasions of the Achæans and the Dorians, which tradition, history and archeology attest Anthropometry witnesses to an invasion of broad heads in the third Late Minoan period (1450–1200 B C) It is to the Dorian inroad, a migration of a people, rather than to the freebooting Achæans, that I attribute the chief part in the broadening of the Cretan head This is best illustrated in the southwest corner of Crete in the eparchies of Sphakia and Selinon The Sphakiots are by tradition and dialect Dorians, and seem to have maintained the purity of their blood by resisting all invaders and by the custom of endogamy They and their neighbors have average cephalic

indices of 80.4 and 80.9 and the broad heads are in the majority of 3 to 2 and 3 to 1. If we assume, as many scholars do, that the Dorians ultimately came from Illyria we have an explanation to hand. The Illyric stock is unmistakable and exceptional in Europe to-day, in that it combines a broad head with a tall frame. In this southwest corner of Crete is a broad-headed people with a stature of 1,709 mm. (cf. Dalmatians 1,711 mm.) whereas the central and western Cretans average 40 mm. less.

A further test made with an instrument I had just invented, the comparison of the sagittal curve of the living head brings out a striking likeness between the brachycephalic Sphakiots, the Albanians (the oldest inhabitants of Illyria) and the Tsakonians, a tribe in the east of the Peloponnesus, 8,000 in number, who still speak a Dorian dialect unintelligible to the Greeks. These three peoples, all with claims to Dorian descent, separated by hundreds of miles, yield exactly similar sagittal curves, and their *normal* types very closely approximate, whereas the contrast to that of the Mediterranean race is extraordinary.

The Social Organization of the Winnebago Indians: DR. PAUL RADIN.

The topics discussed by Dr. Radin included (1) the village organization, (2) the phratries, (3) the clans (animal names, animal descent, clans), (5) the clan functions (clan feasts, clan names), (4) the ceremonials associated with the clans, (5) the clan functions (clan feasts, clan wakes), (6) marriage, (7) death and mortuary customs, (8) the hunt, (9) the warpath.

Dr. Radin closed with a general theoretical discussion of the phratries and clans.

The Religious Ideas of the Winnebago Indians: DR. PAUL RADIN.

This subject was also treated topically: (1) the guardian spirits associated with the ceremonial societies and with the clans, (2) their "nature" (nature deities and "spirit" animals) and the specific powers they control, (3) the "inheritance" of guardian spirits *per se*, and in association with the clan and the ceremonial organization, (4) the "degrees" in the attitude toward guardian spirits, (5) the conception of life, death, future life and transmigration, its bearing on the social organization, (6) the ceremonial associated with the attainment of long life, with death, future life, transmigration, and miscellaneous religious beliefs, (7) the guardian spirits as the basis of the ceremonial organizations and the influence of their disappearance on the type of ceremonial organization, (8) the impossibility of separating the social and religious factors in their attitude toward the guardian spirits and the general conceptions, (9) discussion as to the probable historical development of the religious social complex.

Polynesian Gods: Professor ROLAND B. DIXON.

The characteristics of the four great gods of Polynesia were discussed, and the relative importance of these deities in the different island groups pointed out. Kane, Ku and Lono were suggested as forming a connected group, with Kanaloa quite separate and differing in origin. It was suggested that the latter might probably be derived from a Melanesian deity, whereas the triad showed indications of an origin in Indonesia.

Polynesian and Melanesian Mythology: Professor ROLAND B. DIXON.

The myth incidents of the Polynesian and Melanesian areas were considered in their distribution, and in their relation to the mythology of Micronesia and Malaysia. The general results of this comparison seemed to accord with the theories of migration and cultural origins derived from a study of material culture.

A Pre-Pajaritan Culture in the Rio Grande Drainage: DR. EDGAR L. HEWETT.

On the high bench lands bordering the Chama River on the south, the writer recorded in the summer of 1905 a large number of ruins of a different character from any of the well known ancient Pueblo ruins of Pajarito plateau. During the past summer many more of the same character were noted and surveyed in the Ojo Caliente valley. These ruins consist of foundations of cobble stone inclosing rectangular rooms. Some of the ruin groups are of great extent. A typical group consists of a central circular structure of stone, probably in part subterranean, an open plaza surrounding it, then the foundation walls extending out in all directions. The entire settlement is divided into two parts by a narrow irregular street. That these ruins antedate the great community houses of the Pajaritan culture is shown by the facts that the walls are reduced to the grass level and that these ruins in some cases partly underlie the structures of the latter period.

Abstracts were furnished by some authors who were not able to be present and read their papers. These abstracts are also given.

A Note on the Persistence of some Mediterranean Types: MISS GEORGIANA G. KING.

In Italy and Spain one meets the local frescoes and portraits at times in the streets. I am told that Leonardos and Luinis abound in the Milanese, and a friend of mine has seen a mother and three daughters conspicuously Etruscan in Massa Marittima. Myself I have seen the following and can show photographs for the elder part (I have no modern photographs). In Siena, children like Matteo di Giovanni's. In Viterbo, a woman like the 'Roman School.' In the Emelia, women like Mantegna's and the local school. In Arles, women like the Roman Sarcophagi. In Venice, ecclesiastics like Gentile Bellini's, women like Carpaccio's. In Spain, women like the Lady of Elche.

These last are alike in the matter of figure and carriage and expression, as well as feature.

The Double Curve Motive in Eastern Algonkian Art: Dr. Frank G. Speck.

This paper presents a brief preliminary report of investigations in decorative art being carried on among the tribes of the northeastern Algonkian group, including the Abenadi, Penobscots, Passamaquoddies, Malisits, Micmacs, Montagnais and Nasdapis. The predominant design unit is a figure described for convenience as the "double curve," two opposing incurves. Variations of this elementary figure occur so universally throughout the region discussed, that the double curve motive is really characteristic. While it is also seen occasionally in Iroquois and Ojibway art, it is none the less distinctive of the northeastern Algonkians. Formerly the designs were produced in the moose hair and porcupine quill techniques, and by painting; nowadays most of the examples are seen in beadwork, except among the Nasdapi, where painted decorations still occur. In wood carving and etching on birch bark the more southerly tribes still preserve the old type of decoration.

The main body of material discussed in the paper is based upon collections made among the Penobscots, who are being made the subject of an independent monograph by the writer. Some forty typical forms of the double-curve design, showing different degrees of elaboration, are used. The simplest is the bare double curve, the modifications ranging up through highly complex examples with a score or so of compounded ornaments filling up the interior. In the more modified examples the original double curve unit is sometimes hardly distinguishable on account of the numerous embellishments. Aside from simple ornament, not any particular symbolism has so far been found that would apply to the whole region. Investigations in the field of symbolism have only produced satisfactory results among the Penobscots, where the designs seem to have originally been floral representations with a magical medicinal value through the association of the design with the herbal remedies which play so important a part in the life of these Indians. Judging, however, from the lack of such an interpretation among the Malisits, so far as has been discovered, it would seem, at present, as though the matter will have to be investigated along independent lines in each particular tribal area.

Materia Medica of the Algonkian Indians of Virginia: Mr. J. Ogle Warfield.

This paper treats: (1) Of the subject as recorded by the early authorities. This is far from being full and concise and yet is of value even for the little information it contains. (2) The remnants of these tribes now remaining, having been so closely kept in contact with the English settlers and their descendants for the past three hundred years, have lost all ceremonial functions and ideas connected therewith, and have even lost the limiting of such practise to any particular person or coterie of such persons. That which they use is chiefly in the form of decoctions or "teas" made of barks and roots, which are gathered and made by the mother or grandmother of the family, outward applications are also used. Quite a number of such remedies were obtained. They are not simply recollections of the past, but are used and believed in firmly.

In the absence of Professor Hiram Bingham, his paper on "The Ruins of Choquequirau" was read by Mr. George P. Winship. It and the paper (read by title) by Mr. Stansbury Hagar on "The Four Seasons of the Mexican Ritual of Infancy," are to be published in the *American Anthropologist*. Dr. Edward Sapir's two papers, "The Wolf Ceremonial of the Nootkas" and "The Linguistic Relationship of Nootka and Kwakiutl," will also appear in the *American Anthropologist*.

The papers read, of which the secretary was unable to obtain abstracts were:

Professor Wm. H. Goodyear: "Measurements in 1910 in the Spiral Stairway of the Leaning Tower of Pisa."

Dr. Elihu Grant: "Philistine and Hebrew in Palestine."

Professor E. M. Fogel: "The Survivals of Germanic Heathendom in Pennsylvania German Superstitions."

Professor Arthur C L Brown "Fire and Fairies with Reference to Chrétien's Yvain, vv 4385–4576"

Mr Phillips Barry "A Garland of Ballads"

The following papers were read by title

Professor William H Holmes 'The Place of the Esthetic in Human Welfare'

Professor Junius Henderson "Tewa Ethnozoology"

Mr W W Robbins "Tewa Ethnobotany"

Miss Barbara Freire Marreco "Notes on Tewa Medical Practice"

Mr John P Harrington "The Mesquite and its Uses"

Dr Walter Hough "The Dog in Pueblo, Mexican and Peruvian Mortuary Customs"

Miss H Newell Wardle "The Cradle board in Ancient Mexico"

At one o'clock on Wednesday the twenty eighth, the corporation of Brown University gave a luncheon in the Administration Building, President Faunce receiving The afternoon of the same day was devoted to sight seeing, visits were made to the John Hay Memorial Library the John Carter Brown Library, the Ann Mary Brown Memorial and the Rhode Island School of Design, followed by a reception at the Providence Art Club

GEORGE GRANT MACCURDY

YALE UNIVERSITY,
NEW HAVEN, CONN

FIFTH ANNUAL MEETING OF THE ENTOMOLOGICAL SOCIETY OF AMERICA

THE fifth annual meeting of the Entomological Society of America was held at the University of Minnesota, Minneapolis, December 27 and 28, in the school of mines building The president, Dr J B Smith, presided throughout the session In the absence of the secretary treasurer, Professor J G Sanders was elected secretary pro tem

The following papers were read during the session

"Notes on the Tingid *Leptobyrsa explanata* Heid," E L Dickerson

"Notes on *Sanninoidea exitiosa*," J B Smith

"The Structure of Spermatophores in Crickets," J P Jensen

"The Biological Survey of the Insect Life of Kansas," S J Hunter.

"An Experimental Study of the Death feigning Habits of *Belostoma* (*Zaitha*) *flumineum* and *Nepa apiculata* Uhler," H C and H H Severin

"Announcement of Further Results secured in the Study of Tachinidæ and Allies," C H T Townsend

"Some Suggested Rules to govern Entomological Publications," T D A Cockerell

The report of the committee on nomenclature was received and ordered printed

The report of the executive committee showed that nineteen new members had been received during the year and four lost through death

The result of the mail vote ordered by the society at the Boston meeting was that the annual dues of the society should be two dollars this to include a subscription to the *Annals of the Entomological Society of America*

The following officers were elected

President—Professor Herbert Osborn

First Vice president—Professor Lawrence Bruner

Second Vice president—Professor Alex D MacGillivray

Secretary Treasurer—Professor Alex D MacGillivray

Additional Members of the Executive Committee—Professor J H Comstock, Professor J B Smith, Professor C J S Bethune, Dr W M Wheeler, Dr H Skinner, Dr A D Hopkins

The annual public address was given in Handicraft Hall by Professor F L Washburn, "The Typhoid Fly in the Minnesota Iron Range"

ALEX D MACGILLIVRAY,
Secretary Treasurer

SOCIETIES AND ACADEMIES

THE NEW YORK ACADEMY OF SCIENCES
SECTION OF BIOLOGY

A REGULAR meeting of the Section of Biology was held at the American Museum of Natural History, January 16, 1911, Chairman Frederic A Lucas presiding The following papers were read

Cryptomeric Inheritance in Onagra C STUART GAGER

An abstract of this paper appeared in SCIENCE for February 3, 1911, p 191

Field Notes on Japanese Whales ROY C ANDREWS

The speaker gave an account of a recent seven-months' stay at the Japanese whaling stations, telling of the methods employed in capturing and preparing the whales for commercial use, also of new notes on the habits of finback, blue and sei whales

The latter species, called by the Japanese "sar

dine whale," is referable to *Balænoptera arctica* Schlegel, and although it has been taken for a number of years at the Japanese stations almost no material relating to it is extant. The species is so closely allied to *Balænoptera borealis* Lesson of the Atlantic that further investigation will probably prove it synonymous.

Photographs of the rare North Pacific blackfish (*Globicephalus scammoni*) and of several species of dolphins were also shown. It was announced that a new porpoise of a most peculiar body shape had been secured, and would be described in a future number of the *American Museum Bulletin*.

AT the regular meeting of the section held at the American Museum of Natural History, February 13, 1911, Chairman Frederic A. Lucas presiding, the following papers were read:

Climate and Evolution: W. D. MATTHEW.

The thesis of the paper is as follows:

1. Secular climatic change has been an important factor in the evolution of land vertebrates and the principal known cause of their present distribution.

2. The principal lines of migration in later geological epochs have been radial from holarctic centers of dispersal.

3. The geographic changes required to explain the past and present distribution of land vertebrates are not extensive and do not affect the permanence of the ocean basins as defined by the continental shelf.

4. The theory of alternations of moist and uniform with arid and zonal climates associated, respectively, with partial submergence and extreme emergence of the continental areas, as elaborated by Chamberlin, are in exact accord with the apparent course of evolution of land vertebrates, when interpreted with due allowance for the probable gaps in the geologic record.

5. The numerous hypothetic land bridges in temperate, tropical and southern regions, connecting continents now separated by deep oceans, which have been advocated by various authors, are improbable, inconsistent and unnecessary to explain geographic distribution. On the contrary, the known facts point distinctly to the permanency of the deep ocean basins during the later epochs of geologic time, to the alternate connection and separation of the land areas within the line of the continental shelf and to the continued isolation of those land areas which are surrounded by deep ocean.

These theories are substantially an adaptation of the conservative views of Wallace and other zoologists to the geological theories of Chamberlin. They are defended by a consideration (1) of the nature and extent of the defects in the geological record, (2) of the relations of the zoological regions to each other and the changes effected by elevation or submergence of 100 fathoms, (3) of the principles of dispersal of land animals, (4) of the character of the fauna of oceanic islands (including Madagascar, Cuba and New Zealand) and the degree of probability which attaches to accidental transportation as a means of populating them, (5) of the present and known past distribution of the mammalia, group by group, in considerable detail, (6) of the distribution of the different orders of reptilia in a less detailed manner, (7) of the distribution of birds and fishes, with a few instances from invertebrate distribution which have been especially urged in support of hypothetical bridges, (8) of the objections to such bridges and an interpretation of the real significance of such evidence as has been adduced in support of them.

The speaker believed that the supposed cumulative evidence obtained in various groups of animals or plants for various continental bridges is due simply to identical errors in interpretation running through all such instances. On the other hand, to admit such bridges would seem to involve certain distribution results, which, in the groups which he has studied, assuredly do not exist.

The Limbs of Eryops and the Origin of Paired Limbs from Fins: W. K. GREGORY.

In a skeleton of the temnospondylous amphibian, *Eryops megacephalus* Cope, from the Permian of Texas, which is now being mounted in the American Museum, the limbs are of special interest. Many resemblances to the contemporary reptile *Diadectes* are seen in the stout, long coracoscapula, the short, wide headed humerus, with its very wide, prominent and backwardly directed entocondyle, in the short fore arm, in the very heavy, solid pelvis, stout femur and fully ossified carpus and tarsus. In the character of its limbs *Eryops* was on the whole nearer to *Sphenodon* than to the Urodeles, though far more archaic than the former. As shown by the facets, the humerus and femur were held almost at right angles to the body, the opposite feet being held very widely apart.

The generalized character of the limbs of *Eryops* with respect to those of higher Tetrapoda invite renewed inquiry into the origin of paired limbs from fins. The limbs of known branchio-

saurs and microsaurs do not carry us very far back toward any known type of fish fin In these orders the cylindrical shafts of the long bones, with cartilaginous ends, the cartilaginous carpus and tarsus, the weak shoulder girdle and pelvis suggest a secondary adaptation to aquatic habits

From the work of Thacher, Goodrich, Dean, R C Osburn and others, it seems probable that the paired fins of fishes, like the median fins, have evolved from wide based fins with serially arranged basal and radial cartilages After the formation of the primary shoulder girdle and pelvis and of the pro, meso and metapterygia by fusion and growth of the basals, the various types of paired fins seen in plagiostomes, chimæroids, pleuracanths, dipnoans, crossopterygians and actinopterygians seem to have arisen in each case through the protrusion of the basal cartilages, differential growth and shifting of the radials, and in some cases (*e g*, pleuracanths, crossopterygians, dipnoans) also through the extension of the radials around to the post axial side of the metapterygial axis If the Amphibia have descended from forerunners of teleostomous and dipnoan fishes (as seemed likely) then it was entirely probable that their paired fins had been transformed into limbs through the extreme protrusion of the proximal cartilages, differential growth and regrouping of the more distal cartilages, reduction of the dermal rays This structural change may well have been in large part effected before the air breathing proto amphibians had left the water, owing to the assumption of a new function in the paired fins, *i e*, pushing against solid objects such as roots, in the stagnant water, instead of merely steering A study of the pectoral girdle and fins of *Sauripterus*, a rhizodont crossopterygian of the Upper Devonian, in comparison with those of *Polypterus* and with the limbs of primitive amphibians, had suggested the following provisional homologies

Crossopterygian		*Tetrapod*
"Infraclavicle"	=	Clavicle
"Clavicle" (of Parker)	=	Scapula
"Supraclavicle"	=	Cleithrum
"Coracoid" (hypocoracoid)	=	Coracoid (or pre coracoid?)
"Scapula" (hypercoracoid)	=	Humerus
Proximal basals	=	Radius and ulna
Distal basals	=	Carpals
Radials	=	Metacarpals and phalanges
Dermal rays (derived from scales)	=	Nails, scales

The reduction and loss of the post temporal may have accompanied the freeing of the shoulder girdle from the skull These views differ radically from those of Owen, Parker and Gegenbaur The paired fins of *Sauripterus* were the only ones known that seemed to foreshadow even in a remote degree the paired limbs of the Tetrapoda In the pelvic fin of *Eusthenopteron*, another crossopterygian of the Upper Devonian, differential evolution of the basals and radials had brought about certain remote resemblances to the tetrapod limb The ilium of tetrapods appeared to be a neomorph

L HUSSAKOF,
Secretary

THE AMERICAN CHEMICAL SOCIETY
NEW YORK SECTION

THE sixth regular meeting of the session of 1910-11 was held at the Chemists' Club on March 10, Professor Chas Baskerville in the chair

The election of officers of the section for the session of 1911-12 resulted as follows

Chairman—A C Langmuir

Vice chairman—A B Lamb

Secretary and Treasurer—C M Joyce

Executive Committee—Chas Baskerville, David Wesson, W J Evans and Rudolph Seldner

The following papers were presented

"The Sulphides of Iron," E T Allen

"The Detection of Salicylic Acid," H C Sherman and A Gross

"A Study of the Factors involved in the Qualitative Determination of Barium," E Frankel and L J Curtman

"The Detection of the Platinum Metals by the Glow Reaction," P Rothberg and L J Curtman

"Some New Rare Earth Compounds," Charles James

"Experimental Furnaces for Glass Melts," P C McIlhiney

"Examination of Commercial Oxygen," Reston Stevenson and Chas Baskerville

Before the reading of the last paper, the chairman asked Dr A H Sabin, the first chairman of the section, to preside Dr Sabin, in taking the chair, gave a short account of the early history of the section

Dr McMurtrie had hoped to be present to make some valedictory remarks on the occasion of the last meeting in the original quarters of the Chemists' Club but was obliged to send a written com

munication instead, which was read by Professor Baskerville.

C. M. JOYCE,
Secretary

THE HELMINTHOLOGICAL SOCIETY OF WASHINGTON

THE third regular meeting of the society was held in the zoological division of the Public Health and Marine Hospital Service on January 6, 1911, Dr. Stiles acting as host and Mr. Crawley as chairman.

Dr. Pfender presented a paper entitled "A Few Brief Remarks on Medico-zoological Nomenclature, with Special Emphasis on the Correct Terminology of the Protozoon of Syphilis." The paper points out that persons engaged in preparing new material are in duty bound to use all means that might aid in a clear and correct presentation of their subject. In the medico-zoological field, failure to appreciate this fact has resulted in burdening the literature with numerous erroneous names, the errors being due to medical men and zoologists alike.

In the case of the organism of syphilis, the original errors were made by zoologists, but since being corrected have been persisted in by medical men and other scientific men. Schaudinn in 1905 reported the discovery of an organism which he believed to be the cause of syphilis. Believing that this belonged in the same genus as *Spirochæta plicatilis* Ehrenberg, 1834, he proposed for it the name *Spirochæte pallida,* adopting the emended spelling of Cohn, 1872, for the generic name. About this time Stiles called attention to the fact that Cohn had emended the spelling without reason or authority, hence the correct name was *Spirochæta*. The same year, 1905, Vuillemin decided that the organism did not belong in the genus *Spirochæta* and proposed the name *Spironema,* a change which was accepted by Schaudinn. Vuillemin, however, had not used due care in selecting his generic name, which was preoccupied by Meek, in 1864, for a genus of molluscs, and also, erroneously, by Klebs, in 1892, for a genus of flagellates. Being apprised of this fact, Schaudinn proposed the generic name *Treponema*. This name did not come to the attention of Stiles and Pfender in time to prevent their proposing the generic name *Microspironema,* this last name becoming a synonym under the law of priority. The correct name of the organism of syphilis is therefore *Treponema pallidum* Schaudinn, 1905, and not the popular *Spirochæta pallida*.

The conclusions to be drawn from this case are: (1) it is mandatory that the proper classification of an organism be determined before naming it; (2) every effort should be made to ascertain whether a contemplated name is preoccupied before publishing it; (3) when errors of nomenclature have been made, it is the duty of medical men and other scientists to avoid their repetition, regardless of the popularity of the names; (4) the difficulty of complying with these conditions and with the rules of nomenclature indicates the need of a reform, and this may perhaps be found in the selection of a tribunal of authorities to which proposed names must be submitted for approval and by which the status of names may be settled.

Mr. Hall presented two short notes on gid. The first one, accompanied by the exhibition of a couple of skulls of sheep dying of gid, called attention to the fact that the skulls of yearling sheep and lambs are very thin, and that in the case of sheep having gid, this thinness is increased in the vicinity of the parasite, commonly resulting in actual perforation of the skull in a number of places. The natural thinness and the thinness and perforation resulting from gid make it easy for dogs to get at the parasite and become infected. Experiment shows that they do this either by crushing and eating practically the entire skull, or by inserting the tongue in the foramen magnum and licking out the brain.

The second note dealt with a case of unusual delay in the development of the adult tapeworm, *Multiceps multiceps,* in the dog after feeding the larval gid bladderworm from the brain of the sheep. In this case the dog was killed 82 days after the feeding, and examined post mortem, the feces up to this time having shown no tapeworm eggs or proglottids. Five specimens of the gid tapeworm were found in the dog, the largest having eggs in the uterus, but with no onchospheres as yet developed. The two smaller specimens were less than half an inch long. The dog had been on a diet limited to salt meats or cooked beef and bread, and had had no opportunity to acquire infection with any tapeworm except *Dipylidium*. The usual period of development of the gid tapeworm is given by various authorities as from four to eight weeks. The experiment indicates the unreliability of conclusions based on negative fecal examinations and statements as to the usual time required for the development of a parasite.

Dr Stiles presented a paper entitled "The Influence of Hookworm Disease upon the Apparent Age of Children in the Cotton Mills" There is a wide spread popular belief that many very young children are working in the mills, and that this life results in retarding their physical development and in producing what is called a typical "cotton mill child" Regarding this point, it appears from numerous observations that among the rural tenant whites, children very commonly appear to be younger than they are This is frequently due to hookworm disease retarding development A study of the real and apparent age of 42 people, part of whom were employed in the mills and part not so employed, showed that these persons appeared on an average 3 to 3 8 years younger than they actually were These cases show that the stunted growth of the "cotton mill child" is found in persons who never worked in cotton mills and in those who had never even lived in a cotton mill village All these cases were marked hookworm cases and their stunted growth was apparently due to this disease Considering these facts with other data, the conclusion to be drawn is that the "cotton mill child" like "cotton mill anemia" is a product, not of the cotton mills, but of soil pollution and of the resulting infection taking place before puberty Owing to the presence of hookworm suspects, great care is necessary in judging the ages of mill children

Even after making allowance for hookworm cases in judging ages, there are still a number of young children at work in the mills These are in some cases actually below the legal mill age limit Of 464 hookworm cases and suspects where the exact or approximate age was obtained, 19, over 4 per cent, were below the legal mill age limit (twelve years) of South Carolina, the ages running from nine to eleven years Probably the ratio of children under twelve years of age to the total number of employees is between 2 and 5 per cent

A number of the small children seen in the mills are not employed by the mills, but are "helping" their elders The parent or elder sister is paid for the amount of work turned out With the assistance of a younger brother or sister, who would otherwise be helping with the house work at home, more work can be turned out, thus increasing the earnings The employees are chiefly responsible for this form of evading the law Most mills would prefer not to have these "helpers," but if they are turned out, the family involved moves to another mill. The practise can only be stopped by legal prohibition or mill association agreement, the former being perhaps the better, as the employees resent restrictions made by the mills but accept in more or less good faith the restrictive laws

Mothers often bring children four or five years old to the mills and the children play while the mothers work Often the mother can not leave the child at home, and the kindergarten, provided by some of the mills, is not always open To refuse to allow these children in the mills would increase the difficulty of a widowed or deserted mother in supporting herself

The average child in the cotton mill family is anxious to go into the mills To this end many of them practise deception in regard to their ages

Cases probably occur where parents compel children to lie about their ages, the large number of children claiming to be just above the legal age for mill work points to this

Many of the children have no idea of their exact age and the fathers are often almost as ignorant

It seems probable that a physical examination by local or state medical officials would be better than the present age limit laws In this way many cases of disease would be detected, excluded from the mills and treated It would exclude from the mills all persons who are now justly excluded

Dr Stiles presented a second paper entitled "Is the So called 'Cotton mill Anemia' of the Gulf Atlantic States due to Lint or to Hookworms?" A common explanation of the wide spread anemia among cotton mill hands in certain portions of the United States is that it is due to "breathing in the lint" If this be true, then since the cotton, and hence the lint also, are practically identical in all parts of the country, we would expect to find (1) that the hands in the New England cotton mills show the same type and extent of anemia as those in mills south of the Potomac and Ohio Rivers, (2) that mills of a similar character in eastern, central or western parts of North or South Carolina, or in southern, central or northern parts of Georgia or Alabama, show approximately the same proportion of anemia, (3) that there is the same amount and severity of anemia in a given district among hands who are of the first, second or third generation of mill workers and removed by one, two or three generations from the farm, or if there were

any difference that the anemia would be less among the hands of the first generation, (4) that the greater proportion of severe cases of anemia will be found in such rooms as the card room where there is the greater amount of lint flying around, less severe cases in the spinning room, and no severe cases in the cloth or engine room where there is little or no lint, (5) that persons fresh from the farms will not be very anemic but will become more so the longer they work, (6) and that if the anemia is due to the lint it is not very extensive or severe in the knitting mills, the paper mills, or the orphan asylums, or among medical students or trained nurses, since the persons involved here have little or no contact with lint. Investigation shows that in a general way the contrary is true in the above assumptions.

(1) Not a single case of cotton mill anemia was found in the New England mills, although over 2,000 had been seen in the southern mills. (2) In the Carolinas, Georgia and Alabama, there is a relatively low percentage of cases of anemia in the central clay lands, a greater number of cases and more severe cases are found in places where the hands come from the sand or mountain lands, the worst cases coming from the sand lands. (3) Even where they were located in new mills with better sanitary provisions, the generation fresh from the farms showed a greater percentage of anemia than the hands who were one or two generations removed from the farm. (4) In general the cases of cotton mill anemia are more severe and frequent in the spinning room than in the card room, and the most severe case found in one mill was in the cloth room. (5) Of 59 cases, 39 per cent. had been in the mills less than a year and 61 per cent. had been there more than a year. It seems that 94 per cent. of these cases might theoretically be considered as hookworm infections persisting after removal from soil pollution, and in a number of cases of severe anemia the persons had just entered the mill. (6) The most anemia found in any establishment was in a knitting mill, where 08.8 per cent. had typical "cotton mill anemia." This same anemia was found in paper mills and colleges, and 18 cases were found in an orphanage among children who had never worked in the mills.

The above findings lead to the conclusion that the "cotton mill anemia" has nothing to do with working in the cotton mills. It is due to hookworm disease, contracted in most cases on the farms as a result of the insanitary conditions existing in the rural districts, and brought to the mills from the farms. There is less anemia among mill workers than among the farm tenants, owing to the fact that life under the improved sanitary conditions of the average cotton mill is better from the public health point of view than life as a tenant on a soil polluted farm of the sort from which so many of these people come.

Mr. Crawley presented a paper entitled "Experiments on the Transmission of Trypanosomes by *Glossina*," in which he reviewed the work of Bouet and Roubaud. These workers instituted a series of experiments with *Trypanosoma dimorphon*, *T. cazalboui* and *T. pecaudi*, and the tsetse flies, *Glossina palpalis*, *G. tachinoides* and *G. longipalpis*. It was found that any one of the three species of *Glossina* functioned equally well as host for *T. cazalboui*. Observations with the other trypanosomes have not been completed. Flies bred in the laboratory, and hence free from parasites, were permitted to feed on an infected animal and later were fed each day on a series of "clean" animals. It was found that the first feed or "infecting repast" was followed by a latent period of six days, during which the trypanosomes in the fly are innocuous. The fly then becomes infective and for some time at least the number of trypanosomes within it undergoes a progressive increase. The fly presumably remains infective as long as it lives.

An examination of the infected flies showed that the infection was confined to the proboscis. In the labrum, the flagellates are of the *Leptomonas* type and are fixed to the wall. These develop into trypanosomes which occur in the interior of the hypopharynx. They are either attached to the walls by the ends of the flagella, or free and motile in the interior of the organ. They never ascend beyond the common canal of the salivary glands, but always amass in considerable numbers in the vicinity of the opening of this canal into the hypopharynx.

These trypanosome forms appear in the hypopharynx forty eight hours after the infecting feed, and are abundant by the fourth day. The authors regard these as the infecting elements, and call attention to the fact that the incubation period is not marked by morphological changes, but rather by changes of a physiological nature as regards the virulence of the parasites.

In all, 20 per cent. of the flies fed on infected animals became infected.

THE LOST ARTS OF CHEMISTRY[1]

In addition to chronicling past and present events merely, it pleases the historian from time to time to ascertain, as nearly as he can, by a comparison of present with past conditions and present knowledge and practise with past knowledge and practise, the present condition of mankind of any particular society, in comparison with past conditions. Thus are compared present systems of government with past systems, new religious beliefs with old, modern science with ancient science, present-day arts and manufactures with those of old.

Progress never takes a straight course for any considerable length of time. Nor does it even follow an undulating course in one general direction. But there are advancements and retrogressions, repeated endlessly. And again progress as recorded by history does not represent necessarily the progress of the whole human race. On the contrary, it does not represent even a large part of the human race, but at most an isolated portion of it, and in this isolated portion the progress is recorded not of the whole but of the most advanced individuals only. When we say that the present age is one of great business, scientific and manufacturing or artistic achievements in comparison with the fourteenth century, for example, we mean that a few individuals, very few in fact compared with the total number, have contrived to bring about great results in those fields of human activity. But we must remember at the same time that the majority of indi-

[1] An address delivered before the Minneapolis meeting of the American Chemical Society, December 28, 1910.

viduals may not have been directly concerned in the advance or may not have contributed directly to it at all Indeed, it seems as though the lowest members of the human race to-day are no farther advanced mentally than were their progenitors in recent geologic times Even with rapid progress of the most favored or most enterprising individuals there may be little progress or none in the case of the average of mankind It is not unlikely that at the present day the intellectual gap between the mentally highest and lowest of mankind is greater than at any previous time

In spite of the high intellectual and practical standard reached by the leading men of to-day, from another point of view (called by some the pessimistic) the outlook to-day is far from satisfactory in politics, religion, manufacture or science Whether we consider our all but failing efforts at democracy in the United States or the vacillating and undirected religious tendencies of the people (as shown by mormonism, seventh day adventism, dowieism, christian science, the old theologies or the strange oriental doctrines and ideals of the majority of our people, which fortunately are scarcely put into practise), or if we consider the slow conservatism and plodding course of manufacture and business, including our great untouched problem of the economic distribution of goods, we can not fail to be impressed with the length of the journey which we must sooner or later take, on the road of development

But we may turn from the rather unsatisfactory consideration of politics, religion and business to the consideration of modern science with a rare degree of satisfaction and enthusiasm There, at least, progress is visible, tangible or even obtrusive There, at least, the forward movement does not take the slow, conservative, timid pace of business, nor follow the meandering, uncertain, sentimental path of religion, or the crude meaningless way of politics In that field at least the way is certain, the methods positive, the results satisfying, the application secure and the progress lively Considered by itself, science and the scientific method are the most satisfactory and satisfying things in the possession of the human mind The unfortunate thing—it can not be classed as a criticism—about science is that it has left the multitude untouched With the results of science and the scientific method on every hand forming so large a part of our splendid materialistic civilization, nevertheless the great, the overwhelming majority of people are ignorant of the methods, the aims and the results of scientific inquiry in daily use, and of daily necessity Of even greater import, the scientific method of thought is not a part of their mental equipment

Science and the scientific method have their critics, no less than other excellent things Science is unmoral, cold, heartless, pessimistic, hopeless, often cruel in method, say they The scientific inquirer can well afford to let most of such accusations as these go unchallenged But there is one statement which has been sown broadcast, which springs up in a thousand unexpected places, and which it is worth while to devote some attention to in order to refute it It is the statement that ancient peoples have been possessed of knowledge and of arts unknown to modern times, and indeed people would have us believe that this knowledge and these arts are recoverable by us if at all only with extreme difficulty The "lost arts" is the cry In so far as these so-called lost arts concern applied chemistry let us examine into them, and ascertain if posible whether or not there is truth in the assertions alluded to

In the first place we may well inquire into the origin of the wide-spread belief that the knowledge of various mechanical and chemical arts has been lost to mankind Probably first among the causes is that universal veneration of antiquity which makes gods and saints out of heroes and martyrs of the past, leads to ancestor worship and in general exaggerates the virtues, the crafts and the deeds of valor of olden times Secondly, the delight of many persons in mystery, their tendency toward belief in the mysterious, occult and miraculous, against their better judgment and the facts in the case, have great influence in originating and perpetuating the belief in lost arts Thirdly, among the more general causes, we may place vague statements or sentences which we can not accurately translate in ancient manuscripts Fourthly, the natural reaction against an egotistical age Fifthly, the use by ancient peoples for certain purposes of materials which we would not use to-day on account of their unsuitability This leads to the conclusion that the ancients knew of different and better methods of preparing the material Sixth, it has pleased certain writers and lecturers to insist strongly upon the point that there have been at various times in existence arts no longer known and used One finds brief statements in various books of such import as "they knew how to harden copper" "Their mortar outlasted the stone it cemented" "The degree of perfection they reached in enameling has never since been attained," etc In America the man who has had probably more effect than others in this respect was Wendell Phillips His lecture entitled "The Lost Arts" was first delivered in the American lyceum course in the winter of 1838 During succeeding years the lecture was repeated about two thousand times and was heard by all sorts of audiences throughout the country and at the time and subsequently made a great impression Many persons now living still remember the famous lecture It is difficult to read this lecture to-day and believe that it was seriously intended in certain places by Wendell Phillips, yet I am assured by several individuals who heard it that, although illumined by humor in places, it was, as a whole, seriously intended and received In various lectures Phillips committed many sins against accuracy and truth, but in none more than in the "Lost Arts" He misquoted Pliny in regard to his statements about the origin of glass manufacture—a tale familiar to you all and hardly rising to the dignity of a first-class fable And of all authors, Pliny can least afford to be misquoted, being already overburdened with inaccuracy and unreliability Let me present a few brief quotations from this remarkable lecture

The chemistry of the most ancient period had reached a point which we have never even approached, and which we in vain struggle to reach to day Indeed, the whole management of the effect of light on glass is still a matter of profound study

The second story of half a dozen—certainly five—related to the age of Tiberius, the time of Saint Paul, and tells of a Roman who had been banished, and who returned to Rome, bringing a wonderful cup This cup he dashed upon the marble pavement, and it was crushed, not broken, by the fall It was dented some, and with a hammer he easily brought it into shape again It was brilliant, transparent, but not brittle I had a wine-glass when I made this talk in New Haven, and among the audience was the owner, Professor Silliman He was kind enough to come to the platform when I had ended, and say that he was familiar with most of my facts, but speaking of malleable glass, he had this to say—that it was nearly a natural impossibility, and that no amount of evidence which could be brought would make him credit it Well, the Romans got their chemistry from the Arabians, they brought it into Spain eight centuries ago, and in their books of that age they claim that they got from the

Arabians malleable glass There is a kind of glass spoken of there that, if supported by one end, by its own weight in twenty hours would dwindle down to a fine line, and that you could curve it around your wrist

Cicero said that he had seen the entire "Iliad," which is a poem as large as the New Testament, written on a skin so that it could be rolled up in the compass of a nut shell Now, this is imperceptible to the ordinary eye You have seen the Declaration of Independence in the compass of a quarter of a dollar, written with glasses I have to day a paper at home, as long as half my hand, on which was photographed the whole contents of a London newspaper It was put under a dove's wing and sent into Paris, where they enlarged it and read the news This copy of the "Iliad" must have been made by some such process

Pliny says that Nero the tyrant had a ring with a gem in it, which he looked through, and watched the sword play of the gladiators—men who killed each other to amuse the people—more clearly than with the naked eye So Nero had an opera glass

So Mauritius the Sicilian stood on the promontory of his island and could sweep over the entire sea to the coast of Africa with his nauscopite, which is a word derived from two Greek words, meaning "to see a ship" Evidently Mauritius, who was a pirate, had a marine telescope

The French who went to Egypt with Napoleon said that all the colors were perfect except the greenish white, which is the hardest for us They had no difficulty with the Tyrian blue The burned city of Pompeii was a city of stucco All the houses are stucco outside, and it is stained with Tyrian blue, the royal color of antiquity

But you never can rely on the name of a color after a thousand years So the Tyrian blue is almost a red—about the color of these curtains This is a city all of red It had been buried seventeen hundred years, and if you take a shovel now, and clear away the ashes, this color flames up upon you, a great deal richer than anything we can produce

I feel reasonably sure from what I know of the history of science that the main points made in this lecture were not true in Wendell Phillips's time I know they are not true to-day

To recapitulate the causes of a belief in lost arts appear to be the veneration of antiquity, the belief in the mysterious and occult, inaccuracies in and inaccurate readings of ancient texts, reaction against present-day egotism, the use of unsuitable materials by ancient peoples and the emphasis laid upon ancient skill by half accurate writers

No one could wish to detract from the great, the skilful and the beautiful works of the ancients All we can desire is a proper and clear understanding of their accomplishments

Long before the way was prepared for an approach to chemistry as a science, many were the chemical facts known and used and many the chemical arts and manufactures which arose and flourished The foundations of many of our greatest chemical industries were securely laid long before the science of chemistry lent its aid The industries of cement and plaster, glass, ceramics, pigments, oils and fats, varnishes and lacquers, sugar, fermentation, textiles, paper, dyeing, leather, glue and various metallurgical industries are some of those which were very well developed before the advent of scientific chemistry Indeed, the science of chemistry has found and still finds some of its richest materials in these very industries What can be accomplished by patient manual skill and dexterity is amazing, and it must be conceded that the adoption of exact mechanical processes in our times has lessened the necessity for such skill in many directions It is true also that many ancient peoples and many of the less mechanical modern ones have applied manual dexterity to their arts in such a way that we marvel at the results But it is difficult to find a case where similar application to-day would not yield a similar result Nothing can be considered lost unless it be the demand for and desire to produce works of a certain kind

Again it is true that some arts and

modes of manufacture reach a stage which we may call practical perfection, relatively soon after the initial discoveries are made which give them their first impetus After this point is reached the improvements are few or none (and if any occur, they come from an outside source, as the application of power to the loom) Examples are abundant the hoe and other simple farming implements, the safety bicycle, the sewing machine, the aeroplane It must, of course, be presupposed that suitable materials for manufacture have been previously discovered and are at hand, or can be quickly adapted In such cases as these the opportunities of later generations to develop and improve are meager, but the limitation is not of the inventors, but of the things themselves

For many years the great pyramid of Egypt was held up to the youth in all lands as an example of what had been accomplished by ancient peoples and which could not be duplicated to-day It was held in fact that the ancient Egyptians were possessed of mechanical knowledge and appliances unknown to us We must all concede that the great pyramid is a remarkable, if useless, piece of architecture, laid out with extreme precision and carried to its completion in a masterly way But it turns out that the Egyptians of the Old Kingdom possessed rather limited knowledge of mechanics, not having even developed the movable pulley The great pyramid was built by man-power multiplied many thousand times Finally, can it be considered a greater work than a great railway system or battleship?

That arts have been temporarily lost at least for practical purposes is true The history of industry has not yet been written—possibly it is too great a task—and adequate data have not been collected and hence are not available, but it seems true from the information available that there has been a remarkable continuity in industrial processes in spite of many adverse circumstances

War is probably the greatest cause of breaks in the continuity of manufacturing processes and the arts of peace, and if we are to believe past records, the domination of theological systems or religious dogmatism has been and is the most effective influence in restraining the development of scientific methods of inquiry and consequently progress in the arts On the other hand, commerce and the migrations of peoples have been effective in spreading industries War destroys commerce, but often causes migrations, and hence has been an active influence in the spreading of industry as well as in checking it War has also imposed new civilizations on old, and thus caused an unnatural intercourse between two civilizations, which would naturally result in the extension of knowledge of the industries peculiar to each

Let us examine for a few moments some of the arts claimed to be now lost The knowledge of a process for hardening copper is commonly ascribed to many ancient and prehistoric peoples and is devoutly believed in by many persons Now in the first place if this knowledge was formerly possessed we have no direct evidence of it, for the copper implements which have come down to us are no harder than those we might make ourselves to-day A metal may be hardened in two ways by physical treatment or by alloying it with other metals or substances Copper may be hardened to some extent by hammering, in the same way that many other metals may be hardened The common alloys, bronze and brass, are harder than the pure metal It is probable that ancient peoples used the process of hammering to harden copper and it is certain that they made use of the

alloys of copper first with tin and later with zinc, for many purposes, including tools and implements But because copper and copper alloys were used for implements subjected to rough usage, this does not justify us in concluding that the makers had knowledge of a method for making the metal hard, durable and serviceable The simple and direct explanation is that they had no better material for the purpose at their command, just as in the bone and stone periods bone and stone were the best materials of construction available for tools and implements There is no justification for the idea that ancient peoples knew how to harden copper by means unknown to metallurgists of the present day

The ceramic arts are among the oldest known to mankind and the earliest development of them will probably remain unknown to us They had their beginnings in the bone and stone age, and were probably first practised by women, not by men The first clay vessels may have been clay-covered baskets dried in the sun—we do not know certainly From those early beginnings to the highest types of the art required the labor of many potters, numberless experiments and numberless failures We class ceramics among the chemical industries, and properly so, and yet the ceramic art originated, developed and flourished in many ages and in many parts of the earth without any thought of or aid from the science of chemistry It has always been and still is to a very large extent an empirical industry The essential difference between the pottery practise of ancient times and the most scientific practise of modern times lies in the reproducibility of bodies and glazes by modern methods And yet few chemists in the industry have the temerity to predict how a new clay or glaze will come out of the kiln The potters of long ago, by countless trials of different materials and countless failures, were able to produce certain effects, and they were able to continue the manufacture of similar wares and produce similar effects so long as they were able to obtain materials from the same sources A change of material would almost certainly mean a change in product It must not be forgotten that this same limitation affects the ceramic industry to-day to a very large extent The varieties and properties of clays are almost numberless It is true that potters of all times have been able to devise certain simple tests whereby they have been able to recognize differences and similarities in their raw materials, but these tests were usually of too crude a character to make refined distinctions Now from the very fact that ancient potters were dependent on certain sources of supply for materials to produce certain wares, it was very natural that wares made by a certain people at a certain time were not made by that people at another period, or by different peoples And such a case would probably be classified as a lost art But this can not properly be called a lost art Rather it is a case of lost materials! Given the materials, the wares could be made as at first This in fact has been the work of more recent times—to ascertain by careful analysis the nature of various bodies and glazes and reproduce them Of course the composition is not the whole secret, the heat treatment is almost equally important, and this is a matter for careful physical testing But as the result of modern research and practical experiment it can scarcely be maintained that any body or glaze exists which has not been and can not be reproduced

Glass manufacture is allied to the ceramic industry, and is probably the outgrowth of it In spite of Pliny's fable to

account for the origin of glass making, it is altogether likely that glazes and enamels were the immediate forerunners of glass. Glass manufacture had its origin in Egypt, not far from 2500 B.C. Who shall say that the natural mineral resources of the country (among them limestone, sand and alkalis) were not responsible for its origin there? It spread to the countries east and north of Egypt to Greece and Rome, to Spain, France and more recently to Saxony, Bohemia and Austria—finally over the civilized world. At the present time the data for a history of glass manufacture are probably as complete and available as that for any other of the chemical industries—and possibly more so. The ancient glasses were usually not perfectly transparent but were translucent, in some cases nearly opaque. Transparent glass and particularly transparent glass in large sheets, is a modern production. Many of the ancient glasses and those of early modern times possessed great beauty, considered from the standpoint of the fine arts, although their utility as light transmitters is low. In Greece and Rome glass was used for plates and saucers and other table ware, for pitchers and ornamental objects, as tile in pavements and walls, but scarcely at all in windows. With the advent of transparent glass the production of the translucent varieties did not expand, until finally the art languished in many countries and has but recently been revived for many decorative purposes. It should be noted that the art was never really lost, but the interest in and demand for translucent, tinted and rough-surfaced glass was low.

The dyeing industry is another which dates from the remotest antiquity and which was developed without the aid of scientific chemistry, on an empirical groundwork. However, ancient colors, largely derived from vegetable sources, were reproducible. The use of mordants was practised by many ancient peoples, particularly by the ancient Egyptians, who used them not only for fixing colors, but for producing different shades from the same dye bath. With increasing commerce between nations, new sources of dyes became available and the vegetable-dyeing practise had reached a high degree of perfection when the coal-tar dyes were brought forth in the chemical laboratory to the wonderment of mankind and the revolutionizing of the industry. It has never been claimed, I believe, that the art of dyeing with vegetable colors has been lost or not practised. But there is a strong tendency at the present time to disparage the aniline colors. It is very commonly said and accepted as true that vegetable dyes are superior to coal-tar dyes. That vegetable dyes are fast and coal-tar dyes are not. Persia has recently prohibited the exportation of rugs and fabrics dyed with anything but vegetable dyes, ostensibly to maintain her reputation in the rug industry. Who shall come forward and refute these charges, which are of course all but groundless? There are good and bad dyes, both coal tar and vegetable, and the best dyes must be skilfully used to produce good results. Let us hope that the coal-tar dyes will be increasingly appreciated, and that the time will not come when people will lament the lost art of vegetable dyeing!

But what about the cement and plaster of the ancients which outlasted the ages and even the stones which it held together? In the first place any cement or plaster which was not remarkably durable could not possibly have been preserved to this day. The ancients in various countries and at various times have been well acquainted with lime, burned clay-limestone (hydraulic lime), hydraulic cement, vari-

ous natural cements, puzzolan, and plaster Would it not be strange if among the materials used some would not be found to yield a cement of unusual strength? And if the setting process continued through the ages and conditions were such that weathering did not seriously attack it, the final product yielded would certainly be extremely hard But in any case it is certain that the weaker cements have not come down to us but have been disintegrated long ago The cement which is being made in enormous quantity to-day under scientific control will probably outlast any similar material which the world has seen

But we may go a step farther in our inquiry after relegating the "lost arts" to the same mythological museum which holds the lost Atlantis Not only is it unlikely that there are any "lost" chemical arts, but it is highly probable that ancient peoples were ignorant of many arts attributed to them, and which are well known at the present day Such a misunderstanding could probably best be dispelled by a carefully compiled history of arts and manufactures, particularly ancient arts and manufactures The production of such a book is a consummation devoutly to be wished

I have an idea that it is not a difficult matter to gain a mental picture of conditions in ancient workshops I believe that the mental attitude of artisans has not changed much during the lapse of hundreds or even thousands of years Go into any small shop at the present day where a specialized art or craft is practised and I fancy that you will find the workers there in all essential respects, so far as their craft is concerned, like the craftsmen of distant ages You will find there the same lack of organized knowledge, the same sort of unnecessarily detailed, and elaborated empirical knowledge, the same narrow conservatism and adherence to formulæ and rule-of-thumb methods If you talk to the men you may learn how they learned their craft, of the most skilful members of the craft they have known, if you gain their confidence they may tell you of their past experiments (most of them foredoomed to failure) and of future experiments planned, when time permits or when they obtain material possessed of certain hypothetical properties And you will be impressed by the way results are sometimes accomplished in spite of the use of the clumsiest mental and physical methods of experiment imaginable A typical craftsman will experiment with all the materials he can lay hands on without the slightest scientific consideration of the case, in an effort to produce a certain result These things are interesting and we must hope they will never be altogether lost But our ideal for the present and the future must be a large and adequately organized industry, resting firmly on engineering skill and chemical investigation, operating with a full understanding of all its processes and with assurances of consistent and logical future development and expansion

W D Richardson

THE ELIZABETH THOMPSON SCIENCE FUND

The thirty-sixth meeting of the board of trustees was held in Boston, Mass, on February 10, 1911

The following officers were elected

President—Edward C Pickering
Treasurer—Charles S Rackemann
Secretary—Charles S Minot

Reports were received from the following holders of grants, and were accepted as reports of progress Grant 98, J Weinzirl, 109, A Nicolas, 111, R Hurthle, 119, J P McMurrich, 121, A Debierne, 123, E C Jeffrey, 131, F W Thyng, 133, J F Shepard, 137, C

H Eigenmann, 140, K E Guthe, 144, G A Hulett, 146, M Nussbaum, 149 P A Guye, 150, C A Kofoid, 152, W D Hoyt, 154 J P Munson, 155, H P Hollnagel, 156, R Thaxter, 157, L Mercier, 158, H V Neal

The secretary stated that during the past year no reports had been received from grants 22 and 27, awarded in 1889, 117 (1905), 124 (1905), 142 (1908), and 147 (1909) Grants 107 and 134 were withdrawn, since the recipients were unable to carry on the work for which the grants were awarded, and had repaid the total amount of the grant It was voted to close the records of the following grants, since the work had been satisfactorily completed, and the results published 138, Mme P Šafařík, 141 J T Patterson, 148, C C Nutting, 159, B M Davis, 160, L J Henderson, and to close upon receipt of publications the following 136, H Z Kipp, 161, O von Furth The secretary reported that additional publications had been received from W Dobeick (Grant 153), and from J Koenigsberger (Grant 139), making a total of six publications aided by this grant

An unusually large number of applications was received, and the trustees regretted that they were obliged to decline several which were highly deserving of aid

It was voted to make the following new grants

162 $200 to Superintendent O H Tittmann, Coast and Geodetic Survey, Washington, D C, for observing variations of latitude by means of a photographic zenith tube

163 $200 to Professor R L Moodie, University of Kansas, for phylogenetic studies of Amphibia

164 $200 to Professor J M Aldrich, University of Idaho, for a study of invertebrates, especially insects, found in and about the western salt and alkaline lakes

165 $150 to Professor M E Haggerty, Indiana University, for the study of instinctive reactions in newly born dogs of various breeds, and of the inheritance of those reactions

166 $200 to Professors F C Blake and C Sheard, Ohio State University, for verification of the Kirchhoff Abraham generalization of the Thomson formula for the discharge of a condenser

167 $150 to Dr E Rohde, Heidelberg, Germany, for studies of the metabolism of the mammalian heart

168 $125 to Dr H Freundlich, Leipzig, Germany, for a study of the kinetics of the transformation of aliphatic to aromatic compounds

169 $150 to Professor G A Hulett, Princeton University, for further studies of the electrochemical equivalent (in continuation of Grant 114)

It was voted that grants shall not be made for the purchase of books or ordinary laboratory apparatus, or for living expenses, or for appointments essentially similar to scholarships or fellowships It was voted to request but not to require that all applications shall be type-written

CHARLES S MINOT,
Secretary

HARVARD EXCHANGE OF TEACHERS WITH COLLEGES IN THE MIDDLE WEST

HARVARD UNIVERSITY has arranged an annual exchange of teachers with four of the colleges in the middle west—Colorado College, of Colorado Springs, Colo , Grinnell College, formerly Iowa College, of Grinnell, Ia , Knox College, of Galesburg, Ill and Beloit College, of Beloit Wis Every year, until the arrangement is terminated, Harvard University is to send a professor who will spend an equal portion of half an academic year with each of the four colleges mentioned above, and during that time will give to the students of these institutions such regular instruction in their courses as may be arranged by their faculties The salary of this professor will be paid by Harvard University His traveling expenses will be borne by the four colleges already referred to, and each of them will provide his maintenance while he is in residence The professor will be selected every year by Harvard University, with the approval of the cooperating colleges, and he will go in the first or second half-year, as may be agreed In return, each of the four colleges is expected to send to Harvard University each year one of its younger instructors for half a year, and during that time he will be appointed an assistant in some Harvard course, he will teach

and will be paid as though he were a regular member of the Harvard University staff. Unless by special agreement, he will not be required to give more than one third of his time to teaching, and may devote the rest of it to graduate and research work in any of the departments of the university. Each college is to notify Harvard University of the appointment as early as possible in the preceding year. The arrangement will go into effect in the academic year 1911–12. The first professor of Harvard University to take part in this exchange will be Albert Bushnell Hart, Ph.D., LL.D., Litt.D., Eaton professor of the science of government. His term of service will fall in the second half-year.

SCIENTIFIC NOTES AND NEWS

MR. SAMUEL FRANKLIN EMMONS, eminent for his contributions to the scientific study of ore deposits, died of asthma on the morning of March 28, at his home in Washington, D. C., aged seventy years. On the afternoon of March 30, the members of the United States Geological Survey united in a short memorial service in appreciation of his character and work.

DR. THEOBALD SMITH, professor of comparative pathology in Harvard University, has been appointed visiting professor at the University of Berlin, for the second half of the academic year 1911–12.

PROFESSOR EDWARD L. MARK, director of the Harvard Zoological Laboratory, has been elected a foreign member of the Königlichen Böhmische Gesellschaft der Wissenschaften in Prague.

DR. LAZARUS FLETCHER, F.R.S., director of the British Museum (Natural History), has been elected an honorary fellow of University College, Oxford.

DR. C. G. ABBOT, director of the Astrophysical Observatory of the Smithsonian Institution, will this summer conduct an expedition to southern Mexico to make measurements of the sun's radiation, which will be compared with simultaneous observations on Mt. Wilson. The congress has made a special appropriation of $5,000 for this work.

PROFESSOR HIRAM BINGHAM, of Yale University, will on June 10 leave for a six-months' expedition to Peru. He will be accompanied by a geologist, a topographer and a naturalist and it is hoped by a pathologist. He expects to explore the seventy-third meridian from the Amazon Valley to the ocean.

DR. ROLAND B. DIXON, of Harvard University, is spending the second half of the academic year in the Bureau of the Census in Washington, devoting himself to a statistical inquiry in regard to the Indians.

MR. WILLIAM S. KILNHOLZ has been appointed director of a marine biological laboratory located at San Pedro, Cal. This laboratory is in connection with the Los Angeles schools and the city of Los Angeles expects to spend ten thousand dollars for the laboratory during the next two years.

DR. MARIE C. STOPES, lecturer on paleobotany in the University of Manchester, and Dr. R. R. Gates, of the Missouri Botanical Garden, who met at the Minneapolis meeting of the American Association for the Advancement of Science, were married at Montreal on March 18.

THE April meeting of the American Mathematical Society will be held at University of Chicago on Friday and Saturday, April 28–29. At this meeting Professor Maxime Bôcher will deliver his presidential address, the provisional title of which is "Charles Sturm's Published and Unpublished Work on Differential and Algebraic Equations." Except for the summer meetings, this will be the first united meeting of the whole society since 1896.

DR. S. WEIR MITCHELL delivered the last lecture of the season before the Harvey Society on Saturday evening, April 1, at the New York Academy of Medicine. The subject of the lecture was "William Harvey, the Discoverer of the Circulation of the Blood."

PROFESSOR A. A. NOYES, director of the Physico-chemical Research Laboratories at the Massachusetts Institute of Technology, recently made an address before the College of Science of the University of Illinois, in

which he outlined the research work in progress at the Massachusetts Institute as well as the general policy of the department

Professor Svante Arrhenius, of Stockholm, delivered a lecture before the Scientific Association of the Johns Hopkins University on the evening of March 21 on "The Laws of Adsorption" In this lecture Arrhenius gave an account of some of his recent work in this field

Dr Victor Goldschmidt, professor of crystallography at the University of Heidelberg, has visited the University of Michigan and has given several lectures before classes in mineralogy and geology

Professor W H Freedman, of Pratt Institute, Brooklyn, lectured at the University of Vermont on March 27 on "Some Recent Engineering Achievements," and on March 29 on "Wireless Telegraphy"

Dr Henry P Bowditch's books and scientific apparatus and the sum of $4,000 are bequeathed to Harvard College for the Medical School by the provisions of his will The bequest of $4,000 is "to be added to the fund left by my father, J Ingersoll Bowditch, the income of which shall be expended under the direction of the professor of physiology for the purpose of original investigation"

A bronze tablet in honor of Albert Benjamin Prescott, formerly director of the Chemical Laboratory of the University of Michigan, was put in place at the entry of the new chemical building at the university on March 15

Mrs Ellen Henrietta Swallow Richards, instructor in sanitary engineering in the Massachusetts Institute of Technology, well known for her valuable contributions to sanitary problems, has died at the age of sixty-nine years Mrs Richards was the wife of Dr Robert H Richards, professor of mining engineering at the institute

Edward Fitch Cushing, Ph B (Cornell, '83), M D (Harvard, '88), one of the foremost physicians and public men of the city of Cleveland, died on March 23, at the age of forty-nine years He had practised medicine in Cleveland for the last eighteen years and was professor of the diseases of children in Western Reserve University Dr Cushing was the fourth of his family to follow the medical profession His great-grandfather was a physician in New England, his grandfather, Erastus Cushing, and his father, Henry Kirke Cushing were both physicians in Cleveland His brothers are William E Cushing, a lawyer and trustee of Western Reserve University, Henry P Cushing, professor of geology in Western Reserve University, and Harvey Cushing, professor of surgery in the Johns Hopkins University

At a special meeting lately held in the Berlin Royal Museum of Natural History, as we learn from *Nature*, the committee for the exploration of the dinosaur-bearing deposits of German East Africa exhibited a few of the more remarkable specimens already received The collection consists chiefly of the remains of Sauropoda, some much larger than the gigantic species of North America One humerus measures more than two meters in length, and some of the cervical vertebræ are twice as large as those of Diplodocus The leader of the exploring party, Dr W Janensch, reports the discovery of two new localities in which dinosaurian bones are abundant

The Paris Academy of Medicine, which, in deference to the representations of the British government, recently agreed to designate the disease known as Maltese fever by the term "Mediterranean fever," has decided to adopt as its scientific appellation the name *Melitococcie*

Mrs John H Caswell, of New York, has presented to Trinity College the valuable collection of minerals gathered during his lifetime by the late John Henry Caswell Mr Caswell was graduated from Columbia University in 1865, and after three years' study in Germany became assistant in mineralogy in the newly organized Columbia School of Mines In 1877 his business interests compelled him to give up the career of a scientific man, but he maintained his interest in mineralogy, and his collection became valuable It contains about 4,000 specimens scientifically arranged and illustrates very completely the

typical crystal forms and their variations for a large range of mineral species

That 126 persons bitten by rabid animals in Wisconsin have been treated during the past fourteen months at the Pasteur Institute established in connection with the hygienic laboratory at the University of Wisconsin, is shown by the report of Dr M P Ravenel, the director Over 170 animals supposed to have suffered from hydrophobia were examined by the experts at the laboratory, and the spread of the disease has been checked to a great extent The patients treated came from 61 cities and towns in the state Six persons are under treatment at the present time at the laboratory The entire Pasteur treatment is given the patients at a cost of $25, about one fourth the cost at institutions not conducted by the state Funds are being asked the present legislature sufficient to allow the laboratory to administer the treatment free of charge

The production of natural gas in the United States in 1909, as ascertained by a joint canvass made by the United States Geological Survey and the Bureau of the Census, is estimated by B Hill, in charge of this work, under the supervision of D T Day, to have been $55,000,000, an increase of only about $359,626 over that of 1908 There were no great changes in the industry during the year, the production continuing to decline in Kansas, and an increase being made in Oklahoma and in the Caddo field in Louisiana and in Texas An interesting feature was the supplying of Fort Worth and Dallas from the gas fields of Clay County, Texas For the year 1910 the total production is estimated at $57,000,000, an increase of about $2,000,000 over 1909 During 1910 a feature of great interest was the development of what promises to be a very large supply of natural gas in the Buena Vista Hills, Kern County, Cal, east of the Sunset-McKittrick oil field Arrangements were made and practically completed during the year for piping this gas to Bakersfield and other towns in San Joaquin Valley

An International Congress of the Applications of Electricity is to be held in Turin, Italy, on September 9–20 *Nature* states that this congress, as its title implies, will deal with questions of practical import, so that electrical engineers will be able to participate largely in the discussions The chief endeavor of the organizing committee, which is under the chairmanship of Professor Luigi Lombardi, has been so to draw up the program that the congress may be international in character as well as in name To attain this object, the cooperation of the International Electrotechnical Commission, with its local committees now established in many countries, has been obtained, as well as the assistance of the societies and associations in all countries dealing with electrical matters With the help of these organizations, official reporters have been selected, and already many assurances have been received that numerous papers will be presented to the congress from all parts of the world The initiators of the congress are the Italian Electrotechnical Society and the Italian local committee of the commission mentioned above The congress is under the patronage of the Duke of the Abruzzi, who is the president of the committee of honor, upon which Professor Elihu Thomson and Colonel Crompton, the president and honorary secretary respectively of the commission, have been elected members Papers may be presented in French, English, German and Italian, and the discussions will be carried on in all these languages

The annual meeting of the British Medical Association will be held in Birmingham from July 25 to July 28 The president this year is Dr H T Butlin, consulting surgeon to St Bartholomew's Hospital, and the president-elect Professor Robert Saundby, professor of medicine in the University of Birmingham The president will deliver his address on Tuesday, July 25, the address in medicine will be given on July 26 by Dr Byron Bramwell, president of the Royal College of Physicians of Edinburgh, and the address in surgery on July 27 by Professor Jordan Lloyd, of Queen's Hospital, Birmingham For the purposes of the scientific business of the meeting sixteen sections have been authorized by the council

The subjects to be dealt with and the presidents in each section are indicated below

Anatomy and Physiology—Professor T H Bryce, Glasgow

Dermatology—Dr James Galloway, London

Diseases of Children—Dr Otto Kauffmann, Birmingham

Electro therapeutics and Radiology—Dr Hugh Walsham, London

Laryngology, Otology and Rhinology—Mr Frank Marsh, F R C S, Birmingham

Medical Sociology (including medical inspection of school children, hospital administration, and contract practise)—Dr George Reid Stafford

Medicine—Dr Alfred Carter, Birmingham

Neurology and Psychological Medicine—Dr Edwin Goodall, Whitchurch, Cardiff

Obstetrics and Gynecology—Professor Edward Malins, Birmingham

Odontology—Professor Frank Huxley, Birmingham

Ophthalmology—Mr Henry Eales, M R C S, Birmingham

Pathology—Professor R F C Leith, Birmingham

State Medicine and Industrial Diseases—Professor A B Hill, Birmingham

Surgery—Sir T F Chavasse, Birmingham

Therapeutics, including Dietetics—Sir Robert Simon, Birmingham

Tropical Medicine—Sir Francis Lovell, London

The department of forestry at the University of Montana proposes to organize a summer cruise for students of forestry The party will probably start from Missoula, about July 1, for a tour of the western forest regions, visiting the best stands of timber, viewing the operations of the Forest Service on the national forests, such as timber-sales, planting, reconnaisance, etc, also the operations of private concerns in logging and milling Lectures on different phases of forestry will be given at appropriate points The regions visited will include the northern Rocky Mountains, Puget Sound, the sugar pine country of southern Oregon and the redwood belts of California A feature of the work will be the opportunity afforded for acquiring experience in camping, riding and packing, and familiarity with western conditions The course will continue for about six weeks, and will be open to a limited number Those interested should address Professor J E Kirkwood, University of Montana, Missoula The winter school for forest rangers at the University of Montana has just concluded its second session An extension of the course is contemplated covering two years during the winter seasons Courses are given in various phases of forestry as related to the administration of national forests The staff of instruction includes part of the university faculty and officers of the Forest Service

We learn from *Nature* that a plan for the establishment of an Institute of Technical Optics has been approved by the education committee of the London County Council, and will shortly come before the council The object of this scheme is the establishment in London of an Institute of Technical Optics for the training of opticians and optical instrument makers, and it is also hoped that valuable work may be done in connection with investigations in optical glass The education committee proposes that the council shall grant £35,000 for the building and equipment of the new institute, the site, valued at about £12,000, having been already provided by the Northampton Polytechnic Institute, under the direction of the governors of which the new institute will be maintained To ensure that the work shall be on the best lines, it is proposed to appoint a consultative committee representative of the trade, scientific and other organizations interested The new institute will be maintained from funds at present used to maintain the technical optics department of the Northampton Polytechnic Institute, additional grants from the Board of Education and additional contributions from the London County Council Later it is hoped that, in view of the national character of some of the work which may be developed, assistance may also be obtained from imperial funds In the proposals under consideration, provision is made for the teaching of optical science with its technical applications, and of other subjects of value to the manufacturer and designer of optical instruments, and to the optician

A NEW list of publications of the United States Geological Survey, just issued, contains the titles of more than a thousand books and pamphlets. These reports cover a wide range of subjects. They include not only papers on geology and topography but reports on water resources and on technology. The Geological Survey was the nursery of the United States Reclamation Service and the Bureau of Mines, which now, in full growth, are carrying along successfully work begun by the survey years ago. The survey, however, still continues its work on water resources and includes discussions of technology in its annual volume "Mineral Resources of the United States." A glance at this list will show the great diversity of the subjects considered and the manifold nature of the science of geology. The reports include discussions of geologic chemistry, mineralogy, petrography and paleontology, as well as ore deposition and other matters of very practical importance. Much of the survey's late work has been directed to the study of mineral deposits of economic value. The work done in land classification has not yet found detailed expression in the survey's reports, but some papers prepared as a result of land-classification surveys have been printed annually in bulletins entitled "Contributions to Economic Geology." The list may be obtained by applying to the director of the survey at Washington, D. C.

The statistics of production of gems and precious stones in the United States in 1909, which were collected by the Geological Survey and the Bureau of the Census and have just been published, show a large increase in value over 1908. The total value in 1909 was $534,380, the value in 1908 was $416,063. The increase is due chiefly to larger outputs of turquoise, tourmaline, variscite, chrysoprase, californite and kunzite. The production of a number of precious stones—as beryl, garnet, peridot and topaz—showed a decrease in value. The output of turquoise matrix and turquoise amounted to over 17 tons, that of variscite to over 3½ tons and that of tourmaline to over 2¾ tons. An account of the occurrence and production of gem materials in the United States, with notes on the precious stones industry, has just been published in pamphlet form by the Geological Survey in an advance chapter from "Mineral Resources of the United States, Calendar Year 1909." The pamphlet, entitled "The Production of Gems and Precious Stones in 1909," was prepared by Douglas B. Sterrett and may be obtained free by applying to the director of the survey.

UNIVERSITY AND EDUCATIONAL NEWS

THE legislature of Missouri has recently made appropriations for the state university which include $100,000 for a new laboratory of physics and $60,000 for a laboratory of agricultural chemistry. A building for veterinary science is now in course of construction at a cost of over $30,000. In the recent appropriations the amount appropriated for salaries and current expenses exceeded that of two years ago for similar purposes by $152,000. This amount will be mainly devoted to the increasing of salaries and the enlargement of the faculty.

AN anonymous donor has given Oberlin College the property fronting on South Professor Street in Oberlin, known as the Johnson estate. This comprises approximately twenty-two acres, and is valued at from $35,000 to $40,000.

BY the will of Mrs. Amelia Worthington, of Boston, widow of Bishop Worthington, of Nebraska, a bequest is made to Williams College amounting to $30,000, dependent upon certain contingencies.

MESSRS. MALLINCKRODT, of St. Louis, Mo., announce that they will pay a prize of $500 to a chosen student of chemistry in the Graduate Schools of Harvard University during the academic year 1911–12, on condition that he will serve in the Mallinckrodt Chemical Works in 1912–13 at a suitable salary.

TRINITY COLLEGE has given Cambridge University the sum of £1,000, which is to be used toward the erection of buildings for physiology and for experimental psychology.

THE University of Manchester has received an anonymous gift of £1,000 for promoting research work in medical subjects.

By vote of the board of trustees it was decided last year that at the close of the school year 1911 the academy of the University of Illinois, which has existed since 1876, should be discontinued. Mr. J. P. Gilbert, who was an instructor in zoology, has just been elected head of the department of biology and agriculture in the Southern Illinois Normal at Carbondale. Another member of the academy force, Mr. S. E. Boomer, goes also to the Southern Illinois Normal as head of the mathematics department.

Dr. Hans Zinsser has been promoted to be professor of bacteriology in Stanford University.

The School of Engineering of the University of Pittsburgh announces a new course in mechanical railway engineering which will be under the direction of Mr. D. F. Crawford, general superintendent of motive power, Pennsylvania lines west of Pittsburgh. Students working in this course will combine their theoretical course with practical work in connection with the Pennsylvania lines west of Pittsburgh.

The Bryn Mawr European fellowship has been awarded this year to Miss Helen Tredway, who specialized in physics and chemistry, the president's European fellowship to Miss Mary E. Pinney in biology, and the Mary E. Garret European fellowship to Miss Margaret E. Brusstar, in mathematics.

DISCUSSION AND CORRESPONDENCE

THE ACOUSTICAL ENGINEER

The subject of acoustics as applied to auditoriums deserves a much greater interest on the part of physicists and architects. It is not just, however, to offer criticism without considering some of the reasons for this lack of attention. The physicist realizes that there are many practical problems which constantly tempt him to turn from the performance of his proper function. Moreover he knows that physicists (Sabine and others) have already obtained results far in advance of what are actually utilized by architects to-day. On the other hand, the architect is a man of many troubles and is therefore not inclined to add to his cares by indulgence in experimental work or by applying Sabine's formula to a proposed auditorium. His fee does not cover such expert work and he very naturally attempts to do well that for which he is paid. In short, there is not a sufficient incentive for active interest on the part of either the physicist or the architect.

In spite of the excellent work that has been done, particularly by Sabine, our knowledge of the subject of architectural acoustics is quite limited. It is true (although doubted even by some physicists) that one can not only correct excessive reverberation of an auditorium already constructed, but he can even compute what effect will be had in a proposed structure. This, however, is only a small part of the achievement that will some day be possible. Again our methods of correcting excessive reverberation are not entirely satisfactory either to an architect, or to a layman who desires the remedy to be both permanent and sanitary. It is not for the physicist to improve our present methods of remedying excessive reverberation for this is a practical problem involving structural knowledge. Neither can he be expected to think of the problems of theoretical interest which will sooner or later confront one engaged in applied acoustics.

It seems, then, that the future progress of the subject of acoustics as applied to auditoriums rests in a very large measure upon the activity of what might be termed the "acoustical engineer." This engineer must be an architect of scientific training—one who will be interested alike in the architectural and scientific aspects of the problems. Generally speaking, each auditorium needs a slightly different study and one who is to succeed must have sufficient scientific interest and ability to make the necessary investigations. As so well known, absorbing material applied to the proper area of surface will correct for excessive reverberation. But the amount of area that can be utilized, the character of the interior finish, etc., enter into the

problem. The absorbing material applied should be tested experimentally so that the area covered will give a satisfactory result. Moreover, in cases of well-defined echoes each auditorium will probably require more detailed study.

There are an increasing number of architects in this country who are actively interested in the subject of architectural acoustics, but, with one exception, they have not devoted much time to experimental investigation. This exception is an architect who is devoting his entire time to acoustical engineering. On the other hand, the public does not realize the present knowledge on the subject of architectural acoustics and the architect does not make a serious attempt to educate. The purpose of this note is to call the attention of scientific men to the acoustical engineer and to urge their active interest so far as the education of the public and the recognition of the need of such a consulting engineer are concerned.

G. W. STEWART

THE STATE UNIVERSITY OF IOWA

ACADEMIC EFFICIENCY

TO THE EDITOR OF SCIENCE: Since on several occasions there have appeared in SCIENCE certain criticisms of the Cooke report of the Carnegie Foundation, I hope that you may be willing to publish a brief statement of an opposite view.

Both the report itself and its introduction by Dr. Pritchett state clearly that the opinions of an "outsider" were considered desirable. The recent criticisms of collegiate conditions by many who have not actually studied at first hand the things they condemn seem to have led to the investigation upon which the report is based.

Most of the opinions set forth in the report are precisely those which any well-informed person not connected with a college would hold after a similar study of what actually exists. Moreover, not a few persons on the inside of the college world hold quite similar views. In some ways certain of us go even farther in condemning a part of the things that are more or less characteristic of the college life of to-day.

Especially in trying to fit young men to meet successfully the practical conditions of the real business world, we lament most deeply the woeful lack of the "snap and vigor" which Mr. Cooke found wanting in most of the institutions visited. The "lack of intensiveness" appeals to us much more as a hindrance to the proper preparation of our students for what we know will be required of them in the near future than for any other reason. Not a few of those who employ many highly trained workers positively condemn the college graduate, and will not hire him until he has been whipped into line by sufficient practical experience after his graduation. Some of us know that this is not on account of the subjects which we teach or do not teach in our courses, but rather on account of the general attitude of many of our graduates toward the work that may be assigned them. During the first half year of the cooperative system at the University of Cincinnati, Dean Schneider says he was frequently called to his telephone to listen to something similar to this: "That cub you sent down here thinks this is a university. He won't work." Far too many young men in the colleges and in the collegiate departments of the universities "won't work." Too many students in all of our institutions have no proper conception of the real economic value of their own time or of the opportunities within their grasp. Such ones do not make efficient use of what is provided for them, in funds and in equipments of various kinds. They cut class and laboratory exercises without adequate reasons. They try all kinds of schemes to get out of regular and systematic work. They neglect to do many of the things assigned to them, in many cases up to what they consider the very lower limit of a bare passing grade. Sometimes they ask if they can "cut" this or neglect that and still have a chance to "pass." They give time, energy and most of the thinking that they do, to things which can not be of the least permanent value to them in later life.

Such students do these and many other

things which in the commercial world would not be tolerated for a single day. Some colleges have a much greater proportion of this kind of students, but all colleges have far too many. It is certainly not logical to say that the work of the colleges is so admirable in some respects that the undesirable should be overlooked.

The colleges continually appeal to the public for money and for students. Then why is not this public entitled to consider all phases of college administration and college work? It is considered wise to examine all sides to other questions, and to give the proper relative weight to all things involved. Why should the college question demand a special kind of treatment? Whether instructors and students accomplish as much as they might with the facilities available and with the funds expended is not by any means unimportant. Unless we can claim exemption from any form of criticism, we have no grounds for objection to criticism here.

However true it may be that other things connected with the work of the colleges are more important than those discussed in the Cooke report, no convincing reasons have been given, nor can be given, to show that the bad in our college system can not be improved without the least detriment to the good. In fact to improve in one line must naturally tend to improve others also. To waste time and money will not help any student to become a great scientist or a good citizen. A long tedious and expensive investigation is more likely to bear fruit in the hands of one who has some idea of the value of his own time and the other things he employs. The dilettante in science hinders its progress more than he helps.

I can not see how improvement in the business management of our colleges or improvement in the quality of our student body by sending home those who will not do a reasonable amount of work, or improvement in other lines that might be mentioned, can in the least do other than "tend to assist those conducting these institutions and their students towards the attainment of their own highest ideals in scholarship, character development and culture."

LABORATORY TABLE TOPS

TO THE EDITOR OF SCIENCE: In SCIENCE for February 17, 1911, I notice a short discussion of suitable material for laboratory table tops. Having just found something quite satisfactory, which, so far as I know, is new, the mention of it may be of interest.

The table I have recently tried has a hexagonal top approximately six feet in diameter. The substratum is of pine seven eighths thick and of pieces cross-joined. This substratum is overlaid with a three eighths cover of "asbestolith," a composition of asbestos and cement. This cover of asbestolith was infiltrated with paraffin. To hold the cover the substratum was partially bored to supply small holes which were filled with the asbestolith. This asbestolith is laid on like cement and hardens. It can be made to cover the edge of the top so that the top has the appearance of a solid slab. This top has an absolutely continuous surface, a high degree of resilience, is acid and alkali proof, and can be repaired at any time to original form. The only effect of heat is to melt the paraffin, but this has not proved a serious objection, as it can always be rubbed down to look well. The work was done for me by the Waco Cement Company but no doubt can be duplicated almost anywhere.

RAYMOND H. POND

EXPERIMENT STATION,
COLLEGE STATION, TEXAS

TOTEMISM

IN SCIENCE for February 17 there appeared a report of a paper on "The Totemic Complex" read by myself at a meeting of the Anthropological Society of Washington, on January 17, 1911. I wish to correct some statements made in that report, which might prove misleading. The beginning of the study of totemism does not date back to the sixteenth but to the later half of the nineteenth century. The various features of totemism (exogamy,

tabu, animal descent, etc.), although "they exist separately and independently from one another," are also found associated in totemic complexes. If they were "nowhere found united" and were "not correlated to one another" there would be no totemic problem.

EVIDENCE OF THE ZEBRA IN THE PLEISTOCENE FAUNA OF FRANCE

FROM certain drawings by paleolithic artists, reproduced by Édouard Piette in his work on "The Art Relating to the Reindeer Age,"[1] it would appear that a species of zebra had wandered northward, with other members of the African fauna, during the Pleistocene, at least as far as central France. On plate XXX of Piette's work are reproduced two engraved figures of an animal that seem undoubtedly intended to represent a zebra. In one of these (Fig. 6) only the head and neck appear, while in the other (Fig. 7) almost the entire animal is drawn. The reference to these figures in the accompanying text is as follows:

FIG. 6. Engraving representing the head and neck of a horse like animal with erect mane, delicately striped like the zebra. The stripes are formed by rows of points almost contiguous. One notices in the front of the head a series of marks like chevrons and under the neck, two short parallel stripes. Grotte des Espélungues, A'Arudy.

FIG. 7. Engraving representing an animal like a horse, delicately striped like a zebra, with erect mane, small head having small ears. The stripes are indicated by series of parallel lines or of points. The tail is incompletely drawn. Grotte de Tayngen.

The striping of the hind quarters in Fig. 7, suggests the "gridiron" pattern on the rump of the rock or berg zebra (*Equus zebra*), an existing species now on the verge of extinction, but formerly abundant in the mountainous districts of Cape Colony. Here, however, the likeness ends, for the absence in the engraving of stripe marks on the limbs, the presence of which, clear down to the hoofs, is a character of the above species, would suggest Burchell's zebra (*Equus Burchelli*) as would also the small size of the ears.

[1] "L'Art Pendant L'Age Du Renne," Paris, 1907.

A careful study of these drawings forces one to the conclusion, it seems to me, that a species of zebra was present in western Europe when paleolithic men were engraving the lineaments of reindeer, bison, horse, mammoth, cave bear, woolly rhinoceros and other animals of that strange and interesting time. Surely this ancient artist did not stretch his imagination to so accurately delineate the stripe pattern of a zebra, without having seen it. All of these paleolithic engravings depict an animal most faithfully, even, at times, to minute details. The familiar sight of some beast begat an impulse that found its expression in virile representations of form, remarkably accurate considering the rude and primitive implements for engraving, that were in the hands of these artists of the remote past.

I am not aware of any previous reference to the zebra's former existence in Europe, and I present the above facts simply as evidence coming from the hand of one who without doubt knew and drew some form of zebra that later, like so many other great mammals, vanished from the northern lands.

SPENCER TROTTER

SWARTHMORE COLLEGE, PA.,

SCIENTIFIC BOOKS

Termitenleben auf Ceylon, Neue Studien zur Soziologie der Tiere, zugleich ein Kapitel Kolonialer Forstentomologie. Von KARL ESCHERICH. Jena, Gustav Fischer. 1911. Pp. xvii + 262. 68 text-figures, 3 pls.

This important contribution to our rapidly increasing knowledge of the termites, or "white ants," had its origin in a journey made by Professor Escherich during 1910 to Ceylon, and contains a very interesting account of the behavior of several of the species of that island. Four fungus-growing species (*Termes obscuriceps, redemanni* and *ceylonicus* and *Microtermes globicola*) are considered at length in the opening chapter of the work, their architecture and fungus-gardens being

described in detail and with a number of striking illustrations. The fungus (*Volvaria eurhiza*) which is cultivated and eaten by *T. redemanni* is described and figured in accordance with Petch's investigations published in 1906 in the *Annals* of the Royal Botanical Gardens of Peradenyia.

One of the most interesting portions of this chapter deals with social symbiosis, or the tendency of two species of termites or of termites and ants to inhabit the same nest. Thus Escherich often found *Termes ceylonicus* and *obscuriceps* in the same termitarium but each species inhabited galleries of its own, and although these were mingled they did not inosculate and the two species, when the nests were undisturbed, were always separated from one another by masonry walls. If the insects of the two colonies, however, were made to meet through a breaking down of the walls, their behavior towards each other was decidedly hostile and bitter conflicts ensued.

Singularly enough each of these species had its own fungus-gardens, the chambers containing which were seen to be intermingled when the termitarium was sectioned. Escherich believes that *T. obscuriceps* is the original architect of the nest, whereas *T. ceylonicus* is merely a "Raumparasit." Another case of similar symbiosis is furnished by *Capritermes ceylonicus* and *incola*, each of which may inhabit the nest of *T. redemanni* or *obscuriceps*. In this case, also, the *Capritermes* inhabits small burrows of its own in hills built by the *Termes* and violently attacks the latter whenever it is encountered. The *Capritermes* soldier has extraordinary asymmetrical mandibles by means of which it can jump into the air or hurl its enemies away from the battlefield. Other species, which Escherich found nesting in the mounds of *T. obscuriceps*, are *Leucotermes ceylonicus*, *Eutermes escherichi*, *Eurytermes assmuthi* and *Hamitermes quadriceps*. In all cases these lived shut off from but in very close proximity to their hosts and were always inimical to the latter when the two species were brought together. *Hamitermes*, *Leucotermes* and *Eurytermes* may, however, live in independent nests. Speaking in myrmecological terms, the author concludes that "all the phenomena which we ascertained regarding the living together of different termites belong without exception in the category of 'compound nests,' as opposed to 'mixed colonies.'" Concerning the relations of ants and termites he says that in Ceylon there is scarcely a termitarium which does not harbor ants. The commonest species are *Camponotus rufoglaucus* and its subspecies *paria* and *C. sericeus opaciventris*. These usually inhabit the outer walls or "Mantelregion" of the nest. Escherich was quite unable to observe any such relations as Wasmann has described as existing between South American termites and *Camponotus termitarius* and has called "phylacobiosis" on the supposition that the ant stations itself at the nest-entrance and defends its termite hosts from their enemies. Another common ant in the Cevlonese termitaria is the tropicopolitan *Plagiolepis longipes*, "which lives in nearly every mound, or at least in its immediate neighborhood, flitting like a shadow over the opened portions of the nest and rushing into the galleries and chambers to seize their occupants." In agreement with Wroughton, Escherich describes the habits of a ponerine ant, *Lobopelta ocellifera*, which he calls "die Termitenrauberin par excellence." A whole army of this ant may proceed in a file to a termitarium, break into its galleries and carry away the workers and larvæ in great numbers. An interesting new genus and species of ant, *Pædalgus escherichi* Forel was discovered nesting in the termitaria in small chambers which evidently communicated by means of very slender galleries with the galleries or chambers of the termites. From the great disparity between the size of the queen and that of the worker—the former measuring 5.5 mm., the later 1.1–1.2 mm.—it is inferred that this species must be a thief-ant like the species of *Carebara*, *Oligomyrmex*, *Aeromyrma* and *Solenopsis*, which are also known to live as thief-ants in termitaria or the nests of other ants.

Escherich discusses, in this connection, the habits of a few guests or termitophiles, espe-

cially the carabid beetle *Orthogonius acutangulus*, the swollen or "physogastric" larvæ of which feed on the termites Wasmann had supposed that these larvæ were adopted and fed by the termites in the place of their own huge queens, but Escherich shows that there is nothing to support this view The first chapter of the book concludes with an account of the growth of termitaria and the architectural instincts of the worker and soldier termites

The second chapter is devoted to the habits of the species of *Eutermes*, which have peculiar nasute soldiers, and especially to a charming account of *E monoceros* a black termite which goes forth in long processions fully exposed to the tropical sun to browse on the lichens on tree-trunks and the roofs and walls of houses These processions are indeed "erstaunlich," since they may be several hundred meters long and make the most unaccountable détours, "often three and four times the shortest distance to the feeding grounds" Escherich estimates the number of individuals in a colony of this species at about 200,000 It reminds one of a common European ant, *Lasius fuliginosus*, not only in its dark color and its tendency to form these long processions, but also in its nesting habits Its termitarium is a carton structure and, like that of *L fuliginosus*, situated in a hollow tree-trunk Escherich finds that it also forms on the outside of the trunk an "Abtritt," or latrine near its nest, a black stalactite-like mass which grows gradually as the workers add their feces to it and eventually drops from the tree or dissolves away in the tropical rains It is, however, constantly renewed and is guarded by a cordon of soldiers called by Escherich guards of the latrine ("Abtrittswachter") Since the workers and soldiers of *E monoceros* are blind, Escherich was naturally led to investigate their "homing" instincts Bugnion, who had previously studied this same termite in the same locality, showed that its sense of smell is very acute, and Escherich finds that the workers while they move along discharge from time to time small, black fecal masses which adhere firmly to the substratum like so many fly-specks and serve as guide-posts for the workers and soldiers that follow He concludes, therefore, that the "spoors of the black termites not only have a more intense odor than those laid down by the ants, but are much more stable and persistent" A brief account is added of the habits of some other species of *Eutermes* and especially of the "gallery" termite (*E ceylonicus*), which, like most species of the genus, constructs a gallery or arcade under cover of which it moves from place to place

The third chapter is full of interesting miscellaneous observations and accounts of laboratory experiments It opens with some remarkable notes on the queen termite and contains confirmation of Holmgren's recently published theory according to which the queen termite sweats out on to the surface of her body a substance ("exudate") which is eagerly devoured by the workers and not only keeps the helpless queen supplied with attendants, but, so to speak, binds the whole colony together Not only are the attendant workers continually licking the body of the queen, but Escherich actually saw a worker tear a strap-like piece out of its mother's hide and lap up the liquid exuding from the wound He noticed also that the unwieldy bodies of the queens are often scarred in such a manner as to suggest that this treatment is not unusual The exudate thus obtained by licking or even wounding the queen is often distributed to other workers by regurgitation From these and many other observations Escherich infers "that the eager licking of the queen has its origin not only in the cleansing instinct of the workers, but quite as much in their feeding instincts, or, as Holmgren says, in their 'exudate-hunger'" The queen termite is therefore fed and cherished by her offspring as if she were herself a termitophile, or termite guest, and for the same reasons, and since the other castes—i e, the males, workers and soldiers and their larvæ—also have exudate organs of peculiar structure, Holmgren assumes that the whole problem of caste differentiation in these insects is to be solved with the aid of the exudate theory In

other words, "the amount of exudate determines the amount of food and the latter determines the development of one or the other caste" It is certainly noteworthy, in this connection, that the queen termite, in the egg-laying stage, is clearly afflicted with physogastry, a condition which, as Wasmann has shown, is as characteristic of the guests of termites as the possession of trichodes is characteristic of myrmecophiles

In the same chapter Escherich gives an account of a number of experiments on the behavior of termites brought together from different colonies He found that alien larvæ are much less hostile to one another than are strange imagines (workers or soldiers) As would be expected, the soldiers of different species differ markedly in their methods of attacking and killing their enemies the *Termes* soldier uses its sharp mandibles as a poniard or pair of scissors, the *Capritermes* soldier as a catapult with which to toss its enemies into the air, the *Eutermes* soldier, however, pounds its enemies with its cephalic horn and simultaneously smears their bodies with a sticky secretion from its cephalic gland, the *Coptotermes* soldier reduces its enemy to impotence by throwing over it a milky secretion When termite colonies are invaded by small enemies, the workers often do all the fighting and the soldiers slink away, but larger and more powerful enemies are attacked by the soldiers while the workers behave rather indifferently The main function of the soldiers is to defend the nest entrances

Escherich is of the opinion that the negative phototaxis of termites has been greatly overestimated, but while this may be true of *T redemanni* and *obscuriceps* which were seen building, and of *E monoceros* which was seen foraging "am hellen Tage im grellsten Sonnenschein," the other observations cited do not prove the indifference of termites in general to light Ants, too, are in the main negatively phototactic, though they often forage and build in the bright sunlight

The fourth chapter is devoted to the methods of exterminating termites, a matter of great importance in tropical countries where these insects are often a serious menace to all wooden structures, books, papers, cloth and even to the stems of growing plants (tea, cacao, etc) The following measures are recommended first, stopping some of the main openings of the nest with tow or "waste" soaked with carbon bisulphide and closing all the remaining openings with clay or earth, second (and this is recommended as the most effective treatment), the use of the "universal ant-exterminator," an appliance manufactured by C Henwood & Son, of Durban This consists of a small charcoal stove connected on one side with a hand-pump (resembling that used for inflating bicycle tires) and on the other with a rubber hose provided with a nozzle On glowing charcoal in the bottom of the stove a small quantity of a powder consisting of 85 parts of arsenic and 15 parts of sulphur is placed, the nozzle of the hose is inserted in the entrance of the termitarium and the poisonous fumes which fill the stove are forced into its galleries and chambers by working the pump The hose is then removed, the openings are at once plugged with clay and the nest is left undisturbed for several days If at the end of a week's time some of the termites are found to have survived, the fumigation has to be repeated Escherich describes an interesting apparatus for locating termites, a "Termitensucher" manufactured by Friedrich Suck, of Hamburg, for use in the German colonies This consists of a microphone inserted in a funnel at the end of a steel tube and connected with a telephone receiver When the tube is stuck into the earth the noise made by the crawling termites can be distinctly heard through the receiver even when they are working at a considerable depth in the soil By means of this apparatus termites may be readily located in the tree-trunks of orchards or estates or in the walls of houses and marked for treatment with the arsenic-sulphur fumes

The work closes with the following series of valuable appendices by various authors on the material collected by Professor Escherich in Ceylon, a taxonomic account of the Ceylonese

termites by Holmgren, a similar account of the ants by Forel, descriptions of the termitophilous coleoptera by Wasmann, a description of a new cricket (*Myrmecophila escherichi*) which has become termitophilous, by Schimmer, termitophilous thysanura, myriopoda and coleopterous larvæ by Silvestri, a termitophilous earthworm (*Notoscolex termiticola*) by Michaelsen.

THE ORIGIN OF FIVE MUTATIONS IN EYE COLOR IN DROSOPHILA AND THEIR MODES OF INHERITANCE

The White Eye

In cultures of *Drosophila ampelophila*, that had been closely inbred for a year, a male fly, lacking the red pigment of the eye, appeared. The same stock has continued to produce these white-eyed mutants always of the male sex. A white-eyed father transmits the character to about one fourth of his grandsons, but to none of his granddaughters. In this sense the character is sex limited. The white eye can be transmitted, however, to the females, most readily by breeding any white-eyed male to red hybrids (F_1) out of white by red. White-eyed males and females give pure stock. When a white-eyed female is bred to any wild male all of the female offspring have red eyes and all of the male offspring white eyes. The result shows that the male-bearing sperm of the wild flies lacks at least one of the factors essential for the production of red eyes. This statement does not mean that the male-determining sperm lacks all of the factors essential for producing red, but only that it lacks one of the factors necessary for the production of red. In fact, it is conceivable that all of the rest of the cell may be equally essential for the production of red, but in the absence of one condition (factor) the red fails to develop. It is in this sense that I understand the use of the word "factor" in inheritance, and in the same sense one might employ the word "unit character," although the latter word may seem to imply (from usage) that a particular character is represented entirely by some unit in the germ cells. We are not warranted, I believe, in extending to the results of Mendelian inheritance such an interpretation. Since I have discussed elsewhere the mode of transmission of the white eyes,[1] I shall omit further details here.

The Pink Eye

This eye color has appeared at least twice in cultures in no way closely related to the white-eyed stock. It is not due to a cross between red- and white-eyed flies. The color is much lighter and more translucent than red, and appears to contain more yellow. It is seen to best advantage soon after the flies have emerged. Later it becomes darker and casual observation might mistake it for red. As the flies get old the pink changes to a somewhat purplish color, and this change does not take place in the red eyes, so that with experience there is no difficulty in separating the two colors at all stages. No intermediate condition has been seen despite the fact that thousands of the pink-eyed flies have been examined.

Pink-eyed males bred to wild red-eyed females produce all reds in the first generation. These flies, inbred, have produced in the second filial generation 3,063 reds to 169

[1] Science, July 22, 1910.

pinks, males and females. The reciprocal cross, viz., pink-eyed females and red-eyed males, gives also in the first generation red-eyed individuals only. These inbred have produced 1,133 reds, males and females, and 237 pinks, males and females. The results show that pink is not sex limited. The simplest explanation of the difference between the modes of inheritance of pink and white eyes is found, I think, if we ascribe the factor involved in the formation of pink eyes to some other part of the mechanism than that involved in the formation of white eyes. If I am right in ascribing the sex-limited inheritance of white eyes to some change in one of the sex chromosomes, then the factor for pink eyes must be contained in some other part of the cell, possibly in some other chromosome. That this must be the correct interpretation is borne out by the results of the second cross just given, in which the male-producing sperm of the red-eyed male produces red eyed males. Evidently this sperm adds the necessary factor to the pink-bearing egg to produce red eyes, which would not be the case if the factor in question was present in the sex chromosome which is assumed to be absent from this spermatozoon. The hypothesis also makes clear how important it may be to recognize that different parts of the cell may be involved in producing such a "unit character" as eye color.

The relation of pink to white eyes is extremely interesting. When a pink-eyed female is bred to a white-eyed male all of the offspring have *red eyes*. These inbred produce red-, white- and pink-eyed offspring in the following proportions:

Red eyed females	418
Red eyed males	198
White eyed males	222
Pink eyed females	117
Pink eyed males	35

White eyes appear again in this combination as sex limited. The pink eyes are relatively few in number, and the *females* are about three times as numerous as the males.

The reciprocal cross, viz., white-eyed females and pink-eyed males, gives in the first generation *red-eyed females and white-eyed males*. These inbred produce

Red eyed females	411
Red eyed males	333
White eyed females	377
White eyed males	365
Pink eyed females	76
Pink eyed males	94

In this combination both males and females with white eyes appear in the second generation in about the same proportion as the red-eyed individuals. The pink eyes are again fewer than the other classes, but now the *females* are somewhat less numerous than the males. These peculiar results can, I believe, be accounted for theoretically, but the analysis is too elaborate to give here.

These results indicate that the white eye lacks one factor for red and pink eye, another factor for red. When combined all the elements for red are present. But the second generation shows that the reds formed in this way by recombination differ from the ordinary reds in that they produce reds, pinks and whites. The difference between these artificial reds and the normal reds consists in the presence of one dose of red in the artificial and two in the normal reds (at least in the female). The segregation is a consequence of this heterozygous condition. If this view is correct it should be possible to produce by the proper combinations some pinks and whites that when combined no longer produce reds, but only pinks and whites. I have made such races that have continued for several generations to produce pinks and whites only in very large numbers. In order to discover whether the induced change in this new race has taken place in the white or in the pink, the following experiment was carried out. One of the new pink females was crossed to a white male of the ordinary stock. This combination gave, it will be recalled, with ordinary pinks, red males and females, as stated above. The same thing occurred in the new experiment, showing that the pink had not been changed. On the other hand, when a white male of the new "pink-white" stock was crossed to an ordinary pink

female only pinks and whites were produced. Evidently the change has taken place in the white. If we express the ordinary red color as the outcome of two factors C and R then the *ordinary* whites will be OR while the *new* white will be represented by OO. The tests that I have made so far corroborate this view, giving the combinations expected from the formulæ. Theoretically the new white should behave towards the new pink as a sex-limited character in the same way in which the original white behaved towards the reds, and such, in fact, is the case. Moreover, it is clear why in the one case (white and pink) there should be sex-limited inheritance and in the other (red and pink) a different kind of inheritance, provided, as the facts strongly indicate, that the factor for pink is contained in another part of the hereditary mechanism than the factor for white. In other words, the factor for white (absence of red) is connected with the factor that determines sex, while that for pink is contained in a different part of the cell. It is this evidence that has seemed to me to show that the phenomenon of sex-limited inheritance is due to an intimate physical relation between the sex factors and the other factors in question, and the most obvious connection is that the relation is to be found in the chromosomes that carry both the sex factor and those factors that are sex limited.

The Bright Red Eye

This color arose in hybrids produced by breeding flies with miniature wings to wild stock. A small percentage of the male offspring had bright red eyes. This cross has been repeated a number of times and has always given some bright red-eyed flies. There can be little doubt that it is produced in some way by the cross. I found, it is true, one individual with bright red eyes in the wild stock from which the cross was made, but only once in many hundreds of flies examined, while the production of coral eyes is a constant feature of the hybrids.

The bright red eye is sex limited, as shown by the fact that in certain combinations it has appeared only in the males. When such males were bred to their red-eyed sisters, bright red-eyed females as well as males were produced. When two bright red-eyed individuals are mated they produce only bright red-eyed offspring, and I have a large stock of these flies that originated in this way.

The bright red eye differs from the red eye in being *conspicuously* more brilliant in color. No intermediate condition has been found. The relation between this color and red and pink has not yet been fully worked out.

The Orange Eye

A cross between a white-eyed male and a red-eyed female (heterozygous for pink) produced flies with red, bright red, pink, white eyes, and a few flies with eyes having a faint orange tinge. The eyes are much lighter than pink eyes, and do not seem to intergrade with them. The appearance of the orange color in this and in other cultures followed the appearance in them of the bright red eye, and seems to be connected with the factor for bright red. As yet this relation has not been clearly worked out. Orange bred to orange has given in some cultures stock that has produced many hundred flies with orange eyes only. The orange eye has not been found to be sex limited in any of the many combinations that have so far been made. Thus while white and bright red eye colors are sex limited the other two colors, pink and orange, do not show this form of inheritance. Now that pure cultures of all the stocks have been obtained, their interrelations will be further studied.

The Spotted Eye

On two or three occasions flies appeared in which some of the ommatidia of the compound eye were red and the rest white. The last individual of this kind that appeared was obviously a white fly with about one fourth of the area of one eye red, the rest white. The other eye was entirely white. Unfortunately the fly died before she could be tested. The occurrence of this mutation is of interest in its bearing on the origin of the spotted condition in many of our domesticated animals.

These cases are comparable to heterozygous flies with one long wing and one short,

proportionate—one the dominant the other the recessive type. Two such flies have been bred to the recessive form and have given long- or short-winged offspring—no fly with both types of wing. Inbreeding these longs to shorts again has not yet produced a single fly with both types of wings. Evidently the asymmetrical condition is due to a somatic change that takes place in the development of the individual, a change comparable to that that takes place in the germ cells of Mendelian hybrids. The same explanation applies to the case of the spotted eyes also. The spotted condition appears therefore to be an ontogenetic segregation.

HEREDITY IN INSANITY

THE fact that nervous and mental diseases are often transmitted by heredity was known to Hippocrates and has since his time been amply illustrated by insane-hospital statistics, but the exact conditions under which such transmission occurs have never been fully understood. A recent study has, however, revealed some data which seem to indicate that certain forms of insanity are transmitted from parent to offspring in the manner of a trait which is, in the Mendelian sense, recessive to normal.[1] The accompanying table shows the actual findings recorded in the study here referred to, these findings, it will be observed, are in fairly close correspondence with theoretical expectation, which is as follows:

1. Both parents being neuropathic, all children will be neuropathic.

2. One parent being normal, but with the neuropathic taint from one grandparent, and the other parent being neuropathic, half the children will be neuropathic and half will be normal but capable of transmitting the neuropathic make-up to their progeny.

3. One parent being normal and of pure normal ancestry and the other parent being neuropathic, all the children will be normal but capable of transmitting the neuropathic make-up to their progeny.

4. Both parents being normal but each with the neuropathic taint from one grandparent, one fourth of the children will be normal and not capable of transmitting the neuropathic make-up to their progeny, one half will be normal but capable of transmitting the neuropathic make-up, and the remaining one fourth will be neuropathic.

5. Both parents being normal, one of pure normal ancestry and the other with the neuropathic taint from one grandparent, all the children will be normal, half of them will be capable and half not capable of transmitting the neuropathic make-up to their progeny.

6. Both parents being normal and of pure normal ancestry, all the children will be normal and not capable of transmitting the neuropathic make-up to their progeny.

Types of Mating	Number of Matings	Total Offspring	Neuropathic Offspring	Normal Offspring: Neuropathic Progeny	Normal Offspring: Without Progeny	Normal Offspring: Normal Progeny	Died in Childhood	Data Unascertained
$RR \times RR \infty RR$	3	16	10	0	0	0	5	1
$DR \times RR \infty DR + RR$	19	129	45	14	20	27	20	3
$DD \times RR \infty DR$	5	18	0	8	2	7	1	0
$DR \times DR \infty DD + 2DR + RR$	7	54	12	6	18	10	8	0
$DD \times DR \infty DD + DR$	1	4	0	1	0	3	0	0
$DD \times DD \infty DD$	0	0	0	0	0	0	0	0

D = Dominant. R = Recessive.

RR = Neuropathic subject (nulliplex inheritance).

DD = Normal subject of pure normal ancestry (duplex inheritance).

DR = Normal subject with neuropathic taint from one parent (simplex inheritance).

[1] "Preliminary Report of a Study of Heredity in Insanity in the Light of the Mendelian Laws," by G. L. Cannon and A. J. Rosanoff. Read before the New York Neurological Society, October 4, 1910.

Results similar to those recorded in the table here given have been obtained in a much more extensive study of heredity in feeble-mindedness which was recently reported by Goddard.[3]

STATE HOSPITAL,
KINGS PARK, N. Y.

THE TEXAS CALIFORNIA ARC OF PRIMARY TRIANGULATION

A GREAT arc of primary triangulation more than 1,200 miles in length, extending from central Texas to the Pacific coast, has just been completed by the Coast and Geodetic Survey. It connects the 98th meridian primary triangulation in the vicinity of Weatherford, Texas, with the Pacific coast primary triangulation in the vicinity of San Diego, California.

It is connected with the United States and Mexican Boundary at a number of places and is joined to and correlates a number of detached government surveys. It furnishes the geographic positions on the U. S. Standard Datum, of more than two hundred points which can be used to control all future public surveys within the region traversed.

There are 92 primary stations in the main scheme of this triangulation and, in addition, 38 stations in secondary schemes which provide for the connections with United States-Mexican boundary monuments and existing triangulation. The total area covered by the triangulation is 48,400 square miles, the average length of line east of El Paso is 17 miles, and from that place to the Pacific coast it is 62 miles. The maximum length of line is about 120 miles. The observations were made with a 12-inch theodolite, the pointings being made on heliotropes and acetylene lamps mounted at the stations observed upon. During the progress of the triangulation two primary bases were measured and 24 primary azimuths were observed.

The reconnaissance for this work was made between September, 1907, and February, 1908, and the observing was done in three seasons between November, 1908, and February, 1911. The total work was done in less than three years and six months, and the observations in less than two years and four months.

While the Coast and Geodetic Survey has, in the past, made more rapid progress on primary triangulation in the United States than that made in any other country, yet the rate of progress on the Texas-California arc exceeds that on any other arc in this country and the unit costs per square mile of area covered by the main scheme and per mile of progress are only about one half those of the triangulation between Marysville, Cal., and Tacoma, Wash., the arc for which, previously, these unit costs were the lowest. The accuracy, as measured by the closing errors of triangles of the Texas-California arc, is greater than that specified in the requirements for such work.

The remarkable rapidity of progress and the low cost of the work were largely due to the small amount of camp equipage used by each unit of the party, to the fact that only two officers had charge of field work, the writer on reconnaissance and a portion of the first season's observing, and Mr. J. S. Hill on the remainder of that season's work and that of the succeeding two seasons, and to the services of a most efficient signalman, Mr. J. S. Bilby, who was attached to each party from the beginning of the reconnaissance to the end of the observing. The parties were organized and managed, in the main, in a manner similar to that of the parties engaged on other pieces of primary triangulation done by this survey in recent years, only such changes being made as were necessary to meet new conditions which were encountered in semi-arid and arid sections, much of which was also mountainous.

This arc of primary triangulation will not necessarily be discussed separately by this survey in investigations of the figure of the earth, as were the two great arcs, one extending across the continent along the 39th parallel of latitude and the other paralleling the Atlantic coast from Maine to the Gulf, and known, respectively, as the "transcontinental arc" and

[3] *Amer. Breeders Magazine*, Vol. I., No. 3.

the "oblique arc" In the last two publications by the Coast and Geodetic Survey on investigations of the figure of the earth (entitled, "The Figure of the Earth and Isostasy from Measurements in the United States" and "A Supplementary Investigation in 1909 of the Figure of the Earth and Isostasy") the method was adopted of using the entire connected network of triangulation

THE ITHACA MEETING OF THE SOCIETY OF AMERICAN BACTERIOLOGISTS, DECEMBER 28-30, 1910

Bacteriology in General Education (president's address) V A MOORE

This address is printed in full in SCIENCE, February 24, 1911 (Secretary)

A Bacteriological Museum and Bureau for the Exchange of Bacterial Cultures at the American Museum of Natural History, New York C E A WINSLOW

The Department of Public Health at the American Museum of Natural History has equipped a laboratory to serve as a central bureau for the preservation and distribution of bacterial cultures of both pathogenic and non pathogenic organisms, and particularly of types of new forms and varieties It is hoped that the laboratories of medical schools, colleges, boards of health, agricultural experiment stations, etc, and those engaged in biochemical work of all sorts, will furnish the museum with cultures at present in their possession, and the laboratory is now ready to receive and care for all such cultures It is desired to have the history of the organisms in as full detail as possible and the museum will be glad, where necessary, to pay for the expense of transferring cultures and transcribing records Types of new species and varieties are particularly desired at the present time and as they may be isolated in the future

The laboratory plans also to keep on file descriptions of bacterial species in print or arranged in the form of the standard card and will be grateful for copies of any such descriptions

Descriptions filed in the department will be carefully preserved and living cultures will be kept in good condition, so far as possible, and will be supplied to corresponding laboratories and schools and other institutions which may desire cultures The laboratory, of course, can not undertake to keep on hand difficultly cultivable organisms, such as can only be maintained for a few weeks after isolation from the body, neither can it at present supply virulent cultures of organisms which rapidly lose their virulence under laboratory conditions It should, however, be able to furnish cultures of organisms of all the ordinary types, which can be maintained under cultivation Pathogenic forms will only be sent to properly qualified persons

It is hoped, further, that the laboratory may offer opportunities for work in systematic bacteriology, and facilities will be offered to properly trained workers who may desire to conduct such work at the museum or to obtain cultures for carrying it on elsewhere

The Proposed Microbiological Central Station in Berlin OTTO RAHN

This paper consisted of a review of the efforts put forth in Germany to establish a central station for investigations and distribution of microbiological cultures It was in line with the preceding paper, but indicates that the German policies are more extensive and complete (Secretary)

The Fermenting Capacity of the Average Individual Cell (Bacterium lactis acidi) OTTO RAHN

It is possible to compute approximately the amount of metabolic products formed by one bacterial cell in one hour This unit is called "fermenting capacity" Object of this computation is the separation of the two vital factors of microbial activity, the growth and the fermentation At present, this separation can be accomplished only by a mathematical calculation The fermenting capacity of the average cell is approximately given by the equation

$$X = \frac{S \log b/a}{t(b-a)\log^2},$$

where S is the amount of products formed during the time t, a is the number of cells in the beginning, b the number after t hours The fermenting capacity of the average cell of *Bacterium lactis acidi* is about 0 000,000,001 to 0 000,000,004 mg of lactic acid per hour This amount is of the same order of magnitude as the weight of the cell

Old cultures of *Bacterium lactis acidi*, if transferred into fresh milk, ferment very slowly because the power of multiplication as well as the

fermenting capacity are greatly reduced, both in about the same ratio. Increase of temperature stimulates growth and fermenting capacity. The comparison of a milk culture and a lactose broth culture showed a higher rate of growth in milk, a higher fermenting capacity in broth. Oxygen reduced the total amount of acid produced and in the two strains under study, the fermenting capacity is more influenced than the growth. It was found that transferring in sugar free broth for 32 days in succession did not influence the fermenting capacity at all.

The frequent statement that in young cultures growth takes place without fermentation is not based on actual experiments. The amount of products formed by a small number of cells must necessarily be so insignificant that it can not possibly be detected by chemical analysis. From the time when a chemical proof is possible, the parallelism is evident. There is no indication of a discontinuity. This is proved, however, only for true products of fermentation. Toxins may be secondary products and follow other laws.

A Halophytic Diplococcus: T. D. BECKWITH.

During the summers of 1907 and 1910 the principal cause of the reddening during preparation for market of salted codfish and other gadoid fish appeared to be a diplococcus which could not be isolated by use of standard media. Special media were devised, the first being an infusion of ordinary salted and unpreserved shredded cod flesh (100 parts) with distilled or rain water (1,000 parts) with the addition of 2 per cent. agar agar. The second medium was made by using pickle from the butts diluted once with distilled or rain water and with 2 per cent. agar agar added. The NaCl content of these media averaged 5.25 per cent.

Upon these media at 30° C. in 96 hours salmon pink colonies appeared upon plating out pinkened fish flesh. The predominant colony form was a diplococcus. This coccus is 0.4–0.5 μ in diameter in freshly isolated cultures, later upon repeated transfer during two years' time, it showed swollen involutionary forms sometimes 1.0 μ in size. The adjacent sides of the units of the diplococcus are slightly flattened like the gonococcus. It stains easily with all common formulæ such as carbol-fuchsin and methylene blue. It is Gram positive, non motile, although having a very marked brownian motion. No capsule could be demonstrated, although the colony on immersion in water showed slight zoogloea-like characteristics. It is an obligatory aerobe. Colony is 1–2 mm. in diameter with edge slightly raised. In chromogenesis the colony is salmon pink but color is somewhat lessened after repeated transfer, becoming pinkish white. In pure culture feeble growth appears on standard neutral beef agar but is not fostered by the other common media in vogue.

No description could be found of this diplococcus and it is thought to be a new species. As it appears on the salt flesh of practically all members of that family, the name of *Diplococcus gadidarum* n. s. is proposed.

Later it was demonstrated that sometimes the form may be isolated on A. P. H. A. standard beef agar plus 7–10 per cent. NaCl. Such a method is not at all certain in result, however.

On account of the fact that fish acted upon by this form undergo rapid decomposition due to its effects, and its characteristics are so halophytic tests were made to compare its growth in a saline medium with two most common forms of albuminous disintegration, *B. subtilis* and *B. fluorescens liquefaciens*. The sets of media were prepared by the addition of various per cents. of NaCl to A. P. H. A. standard beef agar with neutral reaction. Plates were incubated 96 hours at 30° C. The following table shows the points of repression of growth of these microorganisms upon such media and demonstrates the strong halophytism of this diplococcus.

Per cent. of NaCl	0	1	2	3	4	5	6	7	10	12.5	15	20
Diplococcus gadidarum	+	+	+	+	+	+	+	+	+	+	+	0
Bacillus subtilis	+	+	+	+	+	0	0	0	0	0	0	0
Bacillus fluorescens liquefaciens	+	+	+	+	+	0	0	0	0	0	0	0

Optimum condition for *Diplococcus gadidarum* n. s. is indicated to be 5–10 NaCl, for *B. subtilis* and *B. fluorescens liquefaciens* 0–1 per cent.

At Gloucester and afterwards in our laboratories, repeated smear preparations made from particles of fish flesh taken from the most reddened portions along the vertebræ where the coloring is most prominent and generally makes its first appearance, showed this diplococcus to be the most prominent form. It seems likely then that this diplococcus is one of the most destructive

agencies in the reddening of prepared salted fish During the seasons of 1907 it was predominant on the samples examined, although it is possible to conceive that varying seasonal conditions of different summers may change the predominant form so that some other one of the various microorganisms as the causal factors of "red fish" may become the most destructive ones This question is worthy of further study

Bacterial Flora in Milk H W CONN

A general résumé of the present status of dairy bacteriology was furnished by this paper, and it also touched upon the significance of bacteriology in the control of municipal milk supplies (Secretary)

Relation of Form of Milk Pail to Germ Content of Milk H A HARDING and J K WILSON

The first important infection of milk occurs during the act of milking

Ordinary milk pails have open tops, 12 or more inches in diameter Many improved pails have been suggested, but few have been favorably received by dairymen

The leading causes for rejection are the excessive height of the pails and the inconvenient size and shape of the opening for receiving the milk

Tests of various pails indicated that a successful pail should not be over 12 inches high and should have an opening of approximately 25 square inches An oval or elliptical opening is more convenient than a round one of the same area

Stocking found that the use of cloths or mechanical strainers on pails was not desirable and that the relative efficiency of small topped pails was greater under poor dairy conditions

Under high grade dairy conditions when a good small-topped pail was contrasted with an ordinary 18 inch open pail the reduction in germ content was more than 50 per cent As such a pail is as convenient to use and practically as cheap as an ordinary pail, there seems to be no reason why it should not be generally adopted

The Influence of the Products of Lactic Organisms upon Bacillus typhosus Z NORTHRUP

This study was taken up first from the standpoint of the longevity of *B typhosus* in sour milk Previous investigations show that the typhoid bacteria in infected milk are generally all killed within twenty four hours after the milk has reached 0 4 per cent lactic acid

Several widely varying types of lactic organisms were obtained from various sources for this study, *B typhosus*, from the laboratory stock culture The typhoid bacteria and a lactic acid producer were grown together in sterile milk after the milk had soured, the combined culture was plated at intervals A special plating medium was used in two succeeding tests for differentiating the typhoid and lactic organisms, one lactic only was inhibited by the bile agar used as a differentiating medium

Assuming that it is the products of the lactic bacteria and not the bacteria themselves which exert the inhibitive influence upon the typhoid bacteria, the plan was formulated of growing the typhoid bacilli in their products alone The lactics were grown in lactose broth, allowed to produce an amount of acid, then filtered through a Chamberland "F" bougie As a result of these experiments, it was found that a certain amount of the acid produced by the typical lactic organisms has greater germicidal properties than the same amount produced by any other type of lactic organism The typical lactic kills *B typhosus* at + 37° acid or 0 3 per cent lactic acid while the acid made by *B bulgaricus* and another strong acid producer reaches nearly twice 0 3 per cent lactic acid in the lactose broth before the typhoid organisms are killed

A comparison was made establishing the relative amount of acid produced in lactose broth and milk by lactic organisms According to these results, + 37° acid, the minimum inhibitive acidity, produced by No 2 in lactose broth, corresponds to + 80° acid or 0 72 per cent acid in milk

Summarizing, if strong lactic organisms are present in large numbers in infected milk, it may be definitely stated that all typhoid bacteria will be killed when the acidity in the milk reaches 0 72 per cent lactic acid

The Use of Fermentation Tests in the Study of the Lactic Bacteria L A ROGERS

It was found that the characters used in describing the lactic bacteria are not distinctive or are too variable to separate this group into sub groups

The curdling of milk is especially variable and uncertain

The fermentation of various test substances was found to be constant and, when properly correlated, to indicate natural grouping

By means of these tests it was possible to separate the 150 cultures studied into three groups Each of these groups was distinguished by fermenting or failing to ferment certain groups of test substances

The Normal Number of Body Cells in Cow's Milk R S BREED and I READ STEDGER

A report on some determinations made at Allegheny College and the University of Gottingen by the use of the direct method of counting these cells devised by Prescott and Breed[1] A series of examinations was made of cream and skim milks obtained in a variety of ways to determine what became of these cells when the milk was separated or centrifuged The results obtained were so variable that the final conclusion was that none of the methods using the centrifuge can be made satisfactory enough to give results of any value so far as determining the number of cells present is concerned A necessary corollary of this conclusion is that all the deductions based on the use of these methods, careful and painstaking as much of this work has been, are worth less so far as they are based on the numerical factor alone A daily examination of the milk of three normal cows extending over a period of six weeks indicates that there may be a cyclic variation in the number of these cells and showed variations in numbers ranging from 0 to 20,000,000 and more in milk which was apparently normal in every particular

What is the Value of Quantitative Bacteriological Determinations in the Control of City Milk Supply H A HARDING

Their educational value is slight because dairymen are unable to translate quantitative results into terms of dairy processes and laboratory workers are also unable to do this until they have located the particular difficulty by other means

As legal standards quantitative results have little value because they fluctuate so widely, dependent upon the technique used A variation of 100 per cent is frequently observed between the results of two equally accepted methods of determination

They are not necessary, since the best results in improvement of city milk supply can be obtained without the aid of quantitative determinations

They are useful as a check upon the work of dairy inspectors and in determining which dairies are most in need of close observation Where the force of inspectors is not adequate to a close supervision of all the dairies, bacteriological determinations will indicate where the inspector's energy can be most wisely employed

Their greatest value is in measuring the sources of infection There is at present a lack of much data and thousands of dollars are being wasted in present attempts at producing sanitary milk because the relative importance of various avenues of infection are not understood

Apparatus for Collection of Deep water Samples PAYN B PARSONS

Description of a sampling apparatus for use in collecting samples of water for bacteriological examination, where the depth of water is very great and the currents are strong

A single rope used for lowering and raising the lead pipe container and for breaking off the neck of the vacuum tube or releasing the stopper

Also a description of an apparatus for the collection of chemical samples and one especially adapted for dissolved oxygen samples, where the samples must be taken in very deep water and the line kept plumb in the currents

Bacteria in the Waters of New York Harbor PAYN B PARSONS

Table giving the average number of bacteria in the water of New York harbor at the surface and at the bottom during 1909

Table giving the average number of bacteria in the water of New York harbor during ebb and flood tides during 1909

Averages of 1,082 examinations of water, made for the Metropolitan Sewerage Commission of New York, are included in the tables

Discussion of present dangers to the health of the people from the vast quantity of sewage dumped into New York harbor, with special reference to bathing and the oyster industry

Intensity of Pollution as shown by Numbers of Bacteria PAYN B PARSONS

A consideration of numbers of bacteria in various sections of New York harbor, including a comparison of the numbers occurring in samples collected in the Atlantic Ocean and in those taken at points where there was a high degree of pollution

Summary of the average number of bacteria in each distinct section of the harbor, during ebb and flood tides

Table showing average numbers of bacteria as compared with the average per cent of saturation with oxygen in the water of the various sections of New York harbor for all depths and tides during 1909 Eight hundred oxygen and 1,082 bacterial analyses, made for the Metropolitan Sewerage Commission of New York, are included in the averages

[1] See *Journal of Infectious Diseases* for 1910

Comparison of numbers of bacteria in mud deposits on the harbor bottom in samples collected from polluted and unpolluted sections.

Relation of channels and shoals to bottom deposits and bearing of this upon the oyster industry.

Biochemical Factors in Soil: M. X. SULLIVAN.

The soil is not an inert reservoir for plant food, but is the seat of physical, chemical and vital actions, the biochemical factors being especially prominent. Numerous bodies which occur in soils and arise either in the metabolic activities of microorganisms or are left in the soil after the decomposition of the plant and animal débris and perhaps occur also as a result of excretion from roots or from cell sloughing, play a considerable rôle in soil fertility. Some of these substances are harmful to plants, some beneficial. Fertilizers do work in soil in modifying the physiological functions of the microorganisms by bringing about suitable conditions for their development, in stimulating or retarding their digestion of inert bodies, and in furthering their enzymotic functions. Soils *per se* have oxidizing and catalyzing properties, while poor soils have these functions in a much lessened degree. Oxidation in subsoils which are of much poorer productivity than the surface soil is usually very slight.

Bacteria of Frozen Soil: H. J. CONN.

Results of work at Ithaca, N. Y., during 1909–10, showing a phenomenal increase in soil bacteria during the winter. Quantitative results already published.[2] Qualitative work includes the study of about 300 cultures.

Quantitative Results.—Increase from 7 millions per gram in November, 1909, to 33 millions in February, 1910, and from 8 in November, 1910, to 22 in December, 1910. These results are new, but are not disproved by previous work.

Possible Explanation.—There seem to be two different groups of organisms, one increasing in warm, the other in cold weather, the former requires so much organic food that a rapid increase is impossible.

Evidence in Support of this Explanation.—

Relation to Moisture Content.—Germ content and moisture content are usually parallel, the exceptions to this rule are such as to suggest an alternation in predominating types.

Relative Numbers of Rapid Liquefiers, Actinomycetes and Slow Growers.—The last group increases in winter.

Qualitative Results.—There are certain organisms present throughout the year. The others appear only at times and show a tendency to reappear at the same season another year. Fall and winter show the greatest diversity of types.

Classification of the types studied in this work.

1. Higher filamentous bacteria. Actinomyces.
2. Rapid liquefiers, producing spores. Mostly of the *B. subtilis* group.
3. Rapid liquefiers, without spores. All but one *Pseudomonas* forms.
4. Slow growers—without spores, producing punctiform colonies, partly show liquefiers, partly non liquefiers.

Medium used in quantitative work: Gelatin, 12 per cent., dextrose, 0.1 per cent., soil extract, 20 per cent. Reaction adjusted with NaOH to 0.5 per cent. acid to phenolphthalein. Soil extract for this medium prepared by boiling 30 minutes with an equal weight of water, then filtering.

Incubation period in quantitative work: 7 days. Temperature of incubation: 19°.

Viability of P. radicicola on Ash maltose agar: S. F. EDWARDS.

During the summer and autumn of 1906, cultures of *P. radicicola* were isolated from the nodules of nineteen hosts, on ash maltose agar. Colonies were transferred to the same medium in Freudenreich flasks which were kept in a darkened cupboard at laboratory room temperature. During the autumn of 1910, plates were made from these old cultures with the result that in fifteen of them the organism was still living. The results are shown in the following table.

In every case in which growth occurred, the colonies were typical, and stained preparations and hanging drops showed the typical characters of *P. radicicola*.

Pot tests in sterile sand were started, using seeds of alfalfa, red clover, peas and beans. At the time of writing, only the peas were sufficiently developed to examine. Of six control plants, not inoculated, three showed no nodules, and three showed 1, 10 and 12 nodules, respectively. Six plants inoculated with the 1906 culture showed 18, 33, 20, 25, 64 and 25 nodules, respectively. Stains from the nodules showed rod and branched forms typical of *P. radicicola*, and plates showed abundant growth in five days on ash maltose agar at room temperature. The work thus far shows evidence that *P. radicicola* retains its virility as well as its vitality after considerable periods of time in stock cultures under laboratory conditions.

Sweet white clover (*Melilotus alba*), medium dried to 4 mm from 24 mm	4	4	14

Studies of Media for the Quantitative Estimation of Bacteria in Water, Sewage, etc STEPHEN DEM GAGE

The Variation in Composition of Beef Infusion —In a former report, the writer called attention to the fact that the variation in the amount of solids in beef infusion made by the standard procedure was as great as or greater than the amount of pepton added in the process of making gelatin or agar media from that infusion At that time (1904) it was suggested that this error might be considerably reduced if the beef infusion were made up to a constant specific gravity The records at the Lawrence Experiment Station show that while the specific gravity of coagulated and filtered beef infusion prepared according to the standard procedure, may vary between 1 100 and 1 005, about one half of the samples have a specific gravity of about 1 006, and this value was selected as a standard Analyses of a large number of samples of beef infusion adjusted to a standard specific gravity of 1 006 show that the range of variation in the total nitrogen and in the total organic and mineral matters in solution has been fully as great as when no correction of the specific gravity was attempted The error in reading specific gravity with a hydrometer may be as much as ten per cent A careful analysis of the records shows that the proportion of samples in which the total solids did not vary more than 10 per cent from the mean was increased from about 55 per cent in the case of samples of the usual beef infusion to over 75 per cent in the samples of infusion with a constant specific gravity, and a similar increase in uniformity is found in the total organic matters and in the total nitrogen In other words, the use of beef infusion of a constant specific gravity is a step toward media of more uniform composition, and toward increased accuracy in bacterial counts

The Influence of Quartz Sand upon Microbial Cultures OTTO RAHN

The object of this paper is to study the influence of soils upon microorganisms The decomposition of liquid media (milk, peptone solution) was compared with that of the same liquid absorbed in quartz sand, and great differences were found Naturally, aerobic processes were greatly increased and anaerobic processes greatly decreased when the liquid was mixed with sand in such proportion as to allow of abundant aeration Both aerobic and anaerobic processes were favored, however, when just enough liquid was added to the sand to keep it entirely submerged This indicates a peculiar influence of the quartz sand upon microbial action which is paralleled by the retardation or inhibition of poisonous effects upon plant roots by mere addition of quartz sand Surface attraction of the microbial products by quartz sand does not account for this phenomenon

Studies in Disinfection of Alfalfa Seeds J K WILSON

Sterile seeds are desirable if not necessary for the study of the relation of bacteria to plant life

Sterile legume seeds may be obtained from ripening pods, but occasionally they are needed when such a supply is not at hand

The utility of alcohol, corrosive sublimate and formaldehyde in providing such a supply has been tested on alfalfa seeds

Sterility of seeds so treated was tested by incubating them in standard bouillon and examining them macro- and microscopically

Seeds immersed in 70 per cent alcohol for 105

minutes were not sterile The effect of this treatment on germination was not tested

Immersion in $HgCl_2$ 1–1,000, for 2 minutes and washing eleven times in sterile water did not result in sterility This treatment did not reduce the percentage of germination of the seeds

Seeds immersed in 10 per cent formaldehyde for 80 minutes were sterilized only in a few instances The germination was reduced 3 per cent

Seeds were first put into 95 per cent alcohol for 10 minutes and then into 10 per cent formaldehyde for periods ranging from 15 minutes to 6 hours Only those treated 6 hours in formaldehyde were sterile The germination of the seeds treated 6 hours was reduced 65 per cent Ten minutes in alcohol did not reduce the percentage of germination

Seeds were first put into water in a vacuum chamber and the pressure reduced to 3 mm for 210 minutes A portion of these seeds, after being placed for 30 minutes in 10 per cent formaldehyde, was sterile, but the seeds did not germinate The vacuum treatment alone did not reduce the percentage of germination

Apparently the air in seeds prevents the entrance of disinfecting solutions and protects the bacteria

Method of Keeping Bacteria from Growing Plants J K Wilson and H A Harding

The main avenue of infection for experimental plants is through the air

Of the many ways which have been suggested for preventing this infection none of them are simple and effective

Harrison and Barlow have published on a method for growing legumes on agar in Erlenmeyer flasks This method can be improved by growing plants in sterile Mason jars, using sterile seeds and earth Exchange of gases is provided for by soldering a ½ inch tube into the metal jar top, plugging the tube with cotton and covering it with an inverted test tube to reduce the chances of contamination and to check evaporation

Alfalfa planted in such jars, in sterile sandy soil to which 10 per cent of water has been added, grew thriftily during four months without being watered or the jars being opened

(The jars exhibited contain alfalfa planted August 13, 1910, and the jars have not been opened since that date)

Bactericidal Properties and Variations in the Agglutinin Content of Antimeningococcic Sera Lawrence T Clark

Serum obtained from the horse which has received subcutaneous injections of first modified and later unmodified polyvalent suspensions of the meningococcus, acquires measurable quantities of agglutinin Intraperitoneal injections of similar suspensions, either mono or polyvalent, produce in the ram a serum of markedly greater agglutinating power

Homologous sera produced from six cultures respectively, by intraperitoneal injections in the ram, gave distinctly specific agglutinative reactions with but one exception—sera 4 and 6 and cultures IV and VI being interchangeable with similar results

Polyvalent antimeningococcic ram serum possesses decided bactericidal activity, as demonstrated by its effect in combination with complement on fresh living suspensions of the meningococcus

Studies on Immunity in White Rats and Mice against Spirochæta duttoni D H Bergey

White rats and mice that have recovered from a well marked infection with *Spirochæta duttoni* have a high degree of acquired immunity against the organism The serum of such immune rats and mice serves to protect normal animals against the infection

The degree of immunity developed is not always absolute, though it is always sufficient to induce a pronounced alteration in the severity and course of the infection If infection occurs, the onset is delayed, the number of organisms in the blood is relatively small, relapses are infrequent, and a fatal termination of the disease is prevented

The protective substances in the blood of the immune animals consist of at least three types of antibody Agglutinins are present early in the disease Bacteriolytic substances are developed as shown by the degenerative changes in the organisms toward the close of the disease Besides these tropic substances are undoubtedly of far greater importance in bringing about the very rapid diminution in the number of organisms in the blood

The final elimination of the organisms from the blood of the infected animals rests upon their englobement by the free and fixed cells of the body through the influence of the tropic substances

Agglutination of B choleræ suis during the Production of the Dorset Niles Serum Ward Giltner

Purpose—An effort has been made to throw some light upon the relation between *B choleræ suis* and hog cholera There has also been considered the possibility of a constant relationship between potency of serum and agglutinative power for *B choleræ suis*

Methods—The macroscopic, test tube method has been followed Cultures were isolated from the spleen of virus hogs At first a bacterial suspension was prepared by washing off surface growth from agar slants with carbol salt solution, later bouillon cultures were diluted with a solution of formaldehyde Blood samples were taken from the tail bleedings or at slaughter or death of pigs Samples of "mixed sera" were preserved in 5 per cent phenol generally

Results—Normal blood serum gave a maximum reaction at a dilution of 1–250 or less

Blood of virus pigs gave a maximum reaction at a dilution of 1–800, but usually less

Blood of pigs treated by the serum simultaneous method gave a maximum reaction at a dilution of 1–500 These pigs were younger than the virus pigs and, other things being equal, young pigs generally possess a blood of less agglutinative power than old pigs

The agglutination reaction appears to be a reaction of immunity since, as a rule, pigs treated by the serum simultaneous method possess a blood of higher agglutinative power if they live (develop immunity) than if they die (fail to develop immunity)

During the process of hyperimmunization agglutinins for *B choleræ suis* increase as the virus injections increase, but not necessarily simultaneously or in the same degree

Of 51 samples of Dorset Niles serum, only 11 gave an agglutination reaction at a maximum of 1–1,000 or less, while 7 agglutinated at 1–50,000

The agglutinative power of a mixed serum may decrease more or less than 50 per cent after 6 to 8 months in cold storage.

Potency of serum can not be measured by agglutinative power in all cases

Sera of high agglutinative power, *i e*, agglutinating at 1–2,000 or above, were potent in 85 71 per cent of cases and not potent in 14 28 per cent, sera of low agglutinative power, *i e*, agglutinating at 1–1,000 or less, were potent in 45.45 per cent of cases and not potent in 54 54 per cent

***Studies on the Filterable Virus of Hog Cholera*:** Chas T McClintock, Walter E King and Robt H Wilson (From the Research Laboratories of Parke, Davis and Co, Detroit, Mich.)

Results of experiments indicate that a relatively short residence of hog cholera serum in the circulatory system of the horse, in some way causes an activation of the virus Horse serum, obtained one half to one hour after the animal has received approximately 140 c c of hog cholera virus, is capable of producing more uniform results when injected into healthy hogs than corresponding dilutions of hog cholera serum in normal horse blood, *in vitro*, and in physiological salt solution The incubation period following the injection of horse serum virus is relatively short

The minimum fatal dose of virulent serum, as represented by a dilution of the virus in physiological salt solution, does not appear to indicate the minimum fatal dose where the dilution is maintained in the form of horse serum virus

From some analogous phenomena relative to the behavior of toxins, it is suggested that the filterable virus of hog cholera may contain a distinct toxin portion

A Discussion of the Preparation and Distribution of Biologic Products: J J Kinyoun

Founded upon the experiences of the author who has been intimately connected with the development in the production of biologic products in the United States, certain inductions of wide application were drawn pointing toward municipal and governmental manufacture and control (Secretary)

Intestinal Bacteriology A Résumé: Arthur I. Kendall

By feeding experimental animals (cats and monkeys) alternately with protein and carbohydrate, respectively, it is possible to demonstrate definite alternations in the intestinal flora both by staining and by cultural methods

These bacterial alternations consist essentially of a definite sequence of proteolytic and fermentative types of organisms In addition to these changes in the type of the intestinal flora as the diet of the host is alternated, certain bacteria are able to accommodate their metabolism to a protein and a carbohydrate regimen, respectively For example, *B. coli* possesses the power of accommodating its metabolism both to a protein and to a carbohydrate diet

This accommodation of metabolism to dietary changes is a fundamental and extremely important property possessed by many bacteria, and it can be utilized therapeutically

In lactic acid therapy it plays a prominent rôle feeding carbohydrate and cutting down protein in patients suffering from the absorption of protein putrefaction products leads to a change in the metabolism in many of the prominent bacteria concerned in the morbid process These organisms attack the sugar in preference to protein, since it has been shown by the writer that fermentation takes precedence over putrefaction in these bacteria

In exogenous infections, such as bacillary dysentery, it also is an important feature, since it is possible to influence favorably the associated bacterial flora by feeding lactose in these cases The lactose is hydrolyzed, and used by the dysentery bacilli and other organisms in the lumen of the alimentary canal Under these conditions the dysentery flora becomes fermentative instead of putrefactive, that is to say, the flora (dysentery bacilli, *B coli* and the streptococcus principally) form acid products instead of toxin and proteolytic products

Some Quantitative Methods of Examining Fecal Bacteria W J MACNEAL

This paper is a summary of the methods employed in studying the fecal bacteria of healthy men already published in *The Journal of Infectious Diseases*, 1909, together with certain additions to the technic made since The essential character in which the procedure is somewhat unique is in the plan of making every one of a large number of experimental results referable to a definite quantity of the mixed fecal flora, so that all the details of the comprehensive examination are quantitatively comparable with each other, and the results of one examination quantitatively comparable in detail with the results of another examination The experimental observations fall under two heads (1) the direct examination including (*a*) gravimetric determination of bacterial substance, (*b*) microscopic count of the bacterial cells by two methods and (*c*) differential count of Gram stained fecal flora, (2) the culture tests including five different sets of plate cultures and one set of separation tube cultures of the mixed fecal flora, three different sets of plate cultures of the fecal spores and a variety of fermentation tube cultures devised not only to show differences in the fermentative activity of the mixed fecal flora, but also and more especially to bring to development and aid in the eventual isolation of various fecal bacteria which may not be found upon the plate cultures For some of the results obtained by these methods those interested are referred to the papers cited above

Tests of the Virulence of Diphtheria Bacilli B L ARMS, M D, and E MARION WADE, B A

The paper gives the technic of the isolation and test and shows

1 The marked variation in the virulence of different strains of diphtheria bacilli isolated from the same culture, showing the necessity of testing several strains before releasing a case on a negative virulence

2 That as a rule if a case is proved positive by the virulence test the organisms retain their virulence as long as they persist, even though the case has completely recovered clinically

3 That where there is an outbreak of diphtheria the "carriers" often harbor organisms, even though no symptoms are present in the host

4 That sometimes the virulence may become enhanced, although this is the exception and seems to be more frequently true of institutional cases

Further Studies on Blackhead in Turkeys PHILIP B HADLEY

This paper presents some of the results of work on the blackhead disease of turkeys conducted at the Rhode Island Agricultural Experiment Station since July 1, 1908 The further investigations indicate that blackhead can not be considered as a specific disease, but that it includes several distinct etiological factors One of these, as first reported, is coccidiosis Another is now found to be infected with a species of flagellated organism These two factors (and perhaps others) may work either together or separately to produce the pathological appearances characteristic of blackhead Multiplication of the flagellates by means of spore formation has been observed in the tissues of the ceca and liver At an early stage of development many of the parasites lose their flagella and become ameboid In the motile stage the flagellates are characterized by the presence of two flagella, a membrane and a short "Achenstab" The length of the motile forms does not exceed 12 μ Encysted forms 12 μ–16 μ were observed A more detailed report of the investigation appears in the *Centralblatt fur Bakteriologie.*

Bacillary White Diarrhea of Young Chicks LEO F RETTGER.

The epidemic type of diarrhea which is characterized in part by a whitish diarrheal discharge, and which is now known as "bacillary white diarrhea," is caused by a bacillus which belongs to the coli typhi group of bacteria It has many

points in common with the typhoid bacillus. It may be cultivated easily on the ordinary laboratory media, but its growth on slant or plate agar is delicate, and very much like that of the *Streptococcus pyogenes*. This peculiar appearance on agar is a great aid in the identification of the bacillus, and hence in the diagnosis of the disease.

This organism, which has been named *Bacterium pullorum*, is present in the intestine, liver, lung, spleen, kidney, heart and unabsorbed yolk of chicks suffering with the disease in question. It is to be obtained most easily from the liver and yolk, when the latter is present.

Feeding experiments conducted on a large scale demonstrated that the disease may be transmitted to young chickens under three days old through infected food and drinking water. Furthermore, chicks may be infected with *Bacterium pullorum* before hatching. These two facts furnish an easy explanation as to the rapid spread of the infection among chicks many of which were normal at the time of hatching.

The mother hen is the source of infection in the egg. The examination of hens from which it was almost impossible to raise chicks, on account of white diarrhea, revealed the fact that the ovaries were infected with *Bacterium pullorum*. The diseased ova were very abnormal. They were discolored, misshapen and of all degrees of consistency. Eggs from those hens had been found to contain the specific bacillus in question in all stages of incubation. Later, a method was devised for identifying the bacillus in fresh eggs which came from infected flocks. Numerous eggs were tested, and the organism was observed in many of them. Thus, a satisfactory method is at hand for determining, without injury to the birds, which hens are infected with *Bacterium pullorum*, and consequently are the source of infection, if their eggs are used for hatching purposes.

Quite recently a pullet which was less than eight months old, and which was one of the survivers of an infected flock, showed the presence of the specific bacillus in the ovary. This discovery completed the cycle of infection. The laying hen is a bacillus carrier. Her eggs harbor the bacillus, and the chicks which are hatched emerge with the organism planted within them. These chicks are the source of infection of other chicks which are normal at the time of hatching. The disease becomes epidemic. The female chicks which survive carry the infection in their body until they are mature laying hens, and the same cycle is begun again, unless intelligent steps are taken to eradicate the infection by methods which are most apparent.

Carbolic Acid in Fowl Cholera: PHILIP B. HADLEY.

The prevalence of fowl cholera in many of the New England states is increasing. An attempt is being made at the Rhode Island Agricultural Experiment Station to devise methods for its prevention or control. Preliminary experiments have involved a study of the effects of subcutaneous inoculations of a 5 per cent. solution of carbolic acid upon fowls previously infected with the organism of fowl cholera, *Bacillus bipolaris septicus*. The results of this work to date have shown that repeated daily subcutaneous inoculations with 5 per cent. carbolic acid, in 3 c.c. amounts, have power to prevent the development of the disease in fowls infected from one to twenty-four hours previously with the cholera organism. The results were approximately the same whether the infections resulted from subcutaneous inoculation of the virus or from the ingestion of virulent material (feeding by glass pipettes). The possible manner of action of the carbolic acid was discussed. A more detailed report of this work appears in Rhode Island Agricultural Experiment Station Bulletin, No. 144.

The Etiology of Contagious Abortion of Cows: W. J. MACNEAL.

The existence of a contagious form of abortion in cattle has been recognized for a long time by practical husbandmen. Nocard (1886) made the first extensive bacteriological investigation of the disease, but failed to identify any microorganism as the cause. Bang (1896) found a small bacillus in the uterine exudate of aborting cows, grew it in pure culture, and produced abortion by injecting these cultures into cows and sheep. The peculiar oxygen requirement of the microorganism for growth in artificial culture was discovered and fully studied by Bang and Stribolt. Subsequently, the same organism has been isolated from cases of contagious abortion of cattle by Preisz (1902) in Budapest, Nowak (1908) in Krakau, McFadyean and Stockman (1909) in England, MacNeal and Kerr (1910) in Illinois, U. S. A., and by Zwick (1910) in Germany.

The microorganism is a very small rod, not motile and without spores. It is Gram-negative. Plate cultures are best obtained by streak inoculation on solidified serum agar, the plates being incubated at 37° in a closed jar from which the oxygen is partly exhausted. This is conveniently accomplished by putting plates of *B. subtilis* in

the jar along with the cultures of the abortion bacillus. The appearance of the colonies is characteristic, and coupled with the behavior toward oxygen is almost sufficient for identification. Subcutaneous injection of active cultures into pregnant guinea pigs causes abortion with great regularity.

Of the various names employed to designate the organism, *Bacillus* (or *Bacterium*) *abortus* Bang, is considered as the correct and appropriate one.

A Method for Determining the Germicidal Value and Penetrating Power of Liquid Disinfectants: ARTHUR I. KENDALL and MARTIN R. EDWARDS.

The method consists essentially of infecting plain agar with 24 hour cultures of *B. coli*, hardening the agar in sterile tubes of 1.5 cm. inside diameter and about 1 meter long, then cutting cylinders from the hardened agar by running it out slowly and sectioning it transversely into cylinders of about 2 cm. long with a sterile knife. The cylinders so obtained are dropped directly into the disinfecting solutions which it is desired to examine, and into 5 per cent. carbolic acid as a standard for comparison. Cylinders from each solution of disinfectant are removed at the end of stated intervals, washed in distilled, sterile water, and then a core removed from the center of each cylinder along the long axis by means of sterile quill tubing (3 mm. in diameter).

These cores so removed are placed in lactose fermentation tubes and incubated at body temperature for several days, making daily examinations for gas formation.

By comparing the results obtained with the various disinfectants with those of the standard carbolic acid, it is possible to formulate a coefficient which expresses the combined germicidal and penetrating power of the disinfectant in question with that of carbolic acid.

All abstracts have been supplied by authors unless otherwise stated.

SOCIETIES AND ACADEMIES

THE PHILOSOPHICAL SOCIETY OF WASHINGTON

THE 690th meeting was held on February 25, 1911, President Day in the chair. Two papers were read:

Some Causes of Variations in the Polarization of Sky Light: Dr. H. H. KIMBALL, of the U. S. Weather Bureau.

The first part of this paper contained a brief résumé of the main features of sky polarization, together with references to some of the theories that have been advanced to account for them. Observations by different investigators were cited to illustrate the character of periodic variations in sky polarization, and a summary was given of observations by the author. These latter include measurements of the percentage of polarization at the point of maximum, *i. e.*, 90 degrees from the sun and in its vertical, as well as observations on the position of the neutral points of Arago and Babinet. They show (1) variations in sky polarization with place, apparently due principally to differences in the intensity of reflection from the surface of the earth, and (2) variations with meteorological conditions.

No connection is apparent between sky polarization and the pressure exerted by the aqueous vapor contained in the atmosphere. Dustiness, or any form of mechanical haze, decreases the percentage of polarization, but by far the most potent cause of such a decrease appears to be optical haze or the diffusion of light by reflection from the boundary surfaces of non-homogeneous layers or currents of air.

All of the observations included in the above summary were obtained when the sky was practically cloudless. Of the ten days on which the lowest percentage of polarization was observed seven were followed by rain before midnight of the succeeding day.

The Nature of the Sun: Dr. C. G. ABBOT, of the Smithsonian Institution.

In the preparation of a forthcoming book on the sun the speaker had attempted to explain solar phenomena on the hypothesis that the sun is completely gaseous, and not possessing the shell of clouds generally assumed to constitute the photosphere. The temperature of the sun seems to be of the order of 6500° absolute centigrade, and the pressure in the iron reversing layer about five atmospheres. In these circumstances it seems highly improbable that matter other than gaseous exists. A continuous spectrum was held by the speaker to be the natural consequence of the immense thickness and considerable pressure of the radiating gas sphere. A sharp boundary exists because the molecular scattering of light prevents the view at the center of the sun's disc from penetrating more than perhaps one thousand kilometers. A view at the sun's edge will be oblique, and to furnish gas one thousand kilometers thick

there will mean a thickness radially of only perhaps one hundred kilometers, which implies an indistinctness of outline of less than a half second of arc, which is not discernible. In consequence of the deeper source of the observed radiation the effective temperature of the source at the center of the sun's disc exceeds that at the sun's edge. Hence the intensity of the radiation falls off from the center to the edge. The diminution of the effective temperature of the source affects short wave rays more powerfully than longer ones, hence the contrast between edge and center is greater for violet than for red, as long known. The granulation of the sun's disc the speaker regarded as evidence of slight differences of temperature from place to place, with attending differences of radiation. He called attention to the fact that such differences of brightness appear most strongly in spectroheliographic photographs with the red hydrogen line, where of course it is out of the question that the effect is due to the precipitation of a cloud. But it is stated by some that the juxtaposition of the gases to empty space must necessarily cause a precipitation of a cloud by cooling. The speaker drew attention to the existence of water vapor without clouds in many regions of the earth's atmosphere, and to the existence of steam without a cloud for some distance above the stack of a locomotive. The question of cloudy precipitation depends upon the rate of supply of heat to take the place of energy radiated away, and on the rate of change of density of the gas at the boundary. A cloud is not a necessity. Many other points were discussed.

(The foregoing abstracts are by the respective authors of the papers.)

R. L. Faris,
Secretary

THE GEOLOGICAL SOCIETY OF WASHINGTON

At the 238th meeting of the society, held at the Cosmos Club on Wednesday evening, January 25, 1911, under informal communications, Mr. C. W. Hayes exhibited a series of specimens illustrating the growth of concretions of different composition under a variety of conditions.

(*a*) Calcite concretions from the famous Dos Bocas oil well, south of Tampico, Mexico. This well now forms a great caldron about 36 acres in extent. The ebullition due to the escape of gas, which a year ago was continuous, is now intermittent, having a period of about two hours. The well still yields a large quantity of hot (160° F.) salt water heavily charged with lime and a small amount of heavy oil in the form of a frothy emulsion. The water deposits lime carbonate partly in concretionary form. The concretions, from .5 to 1.5 inches in diameter, being kept in motion by the ebullition in the caldron are almost perfect spheres, made up of very thin concentric layers.

(*b*) Bauxite concretions from the Rome district in northwest Georgia. The formation of these deposits has been ascribed to hot spring action and the conditions during their deposition were probably analogous to those seen in the Dos Bocas well. Instead, however, of being charged with lime in solution, the water contained aluminum hydroxide in suspension and this was deposited in concentric layers forming the bauxite concretions.

(*c*) Calcite concretions from San Antonio, Tex. These occur in great abundance in the "telpetate" or "caliche," a widespread chalky limestone formation, produced at or near the surface in semi-arid limestone regions by the ascent of water through capillary action and evaporation with deposition of the dissolved salts. Ordinarily the deposit has a platy structure, but in places, as at San Antonio, it is strongly concretionary.

(*d*) Bauxite concretions from the Little Rock district, Ark. These deposits are similar in form and possibly analogous in origin to the telpetate of San Antonio. The concretions are nearly indistinguishable from those of San Antonio, although entirely different in composition.

Regular Program

The Topographic Development of the Catskill Mountains: H. E. Merwin.

The Catskill Mountains and the adjacent region have the structure of a coastal plain with a very resistant thick member at the top. The Hudson-Mohawk valley developed as a subsequent valley in the weaker lower member that outcropped along the borders of the Adirondack-Taconic old land. The Hudson became superposed upon the complex structure of the Highlands which were buried beneath the coastal plain series. This river seems to have had its course well established by the close of the Paleozoic so that it was antecedent to the folded structure beneath and east of the Catskills.

The topography of the northeastern Catskills, though originally of the peak and spur type characteristic of mature plateaus, is now strongly influenced by the southward dip of the rocks. The drainage of this part of the Catskills was originally westward through the Delaware and Susque

hanna rivers, but long after the uplift of the Cretaceous peneplain the Schoharie captured this drainage.

In the southern and western Catskills the streams are still working in massive rocks, developing the plateau type of topography

The Iron Ores of Sweden WALDEMAR LINDGREN

Mr Lindgren discussed nature and origin of the principal iron ore deposits and exhibited numerous specimens

EDSON S BASTIN,
Secretary

THE BOTANICAL SOCIETY OF WASHINGTON

THE 71st regular meeting was held at the Cosmos Club, Tuesday, March 7, 1911, at 8 00 P M President W J Spillman presided Thirty two members were present Mr H C Skeels was elected to membership

Mr W A Orton discussed current dictionary definitions of the term "genetics" and showed that the usage attributed to Ward in the new Century is faulty, as that author proposed the term as an antithesis of "telics" and did not extend it to other phenomena of evolution The usage in the new Webster was held to be faulty in that it does not convey the new view point of scientific experimentation The term was thus newly defined "*Genetics*—the application of scientific methods to the study of evolutionary problems, the investigation, in an exact manner and by experimental means, of the facts pertaining to heredity, variation and allied subjects"

The following papers were read

Studies of the Life History of the Head Smut of Sorghum ALDEN A POTTER

Attempts at preventing this smut by seed treatments have failed Numerous inoculation experiments have been performed, but neither local infection, as in corn smut, seedling infection, as in the kernel smuts, nor floral infection, as in the loose smuts of barley and wheat, has been demonstrated No theory of local infection can be entertained, however, since detailed histological study has shown that the host plant is affected as a whole Since the infection is general, then, it must take place at an early stage

Peculiar floral alterations were shown to be caused by the smut and to contain the smut mycelium, and it was suggested that some grains may develop with the fungus in them and the smut, therefore, be hereditary as is the fungus in certain *Lolium* species

Dimorphic Leaves of Cotton and Allied Plants O F COOK

This paper reported the existence of a definite dimorphism of leaves in an Egyptian variety of *Hibiscus cannabinus* The basal leaves are simple, but there is an abrupt transition to deeply lobed leaves near the middle of the stalk A second Egyptian variety has all the leaves simple Parallel variations of leaf forms exist in cotton, okra and *Ingenhousia*, a wild relative of American upland cotton, found in Arizona and Mexico The so called okra varieties of upland cotton, with narrow lobed leaves, correspond to the dimorphic Egyptian variety of *Hibiscus cannabinus* Hybrids between okra cottons and broad leaved varieties have shown intermediate forms of leaves in the conjugate generation and Mendelian segregation in the perjugate generation Dimorphism and Mendelism were treated as analogous forms of alternative expression of characters, the current theory of alternative transmission being considered unnecessary

Plant Remains Composing Coals DR R THIESSEN

A brief review of the literature on the microscopic investigations of coals was given, in which the views of Bertrand and Renault and Potonié were dwelt upon

Since every interpretation of any investigation must agree with every known scientific fact, in the present investigation on coal the structure, organization, morphology and chemistry of the living as well as of fossil plant forms had to be considered Plant components of coals may be divided into two classes those less resistant to chemical agencies, and those less easily or very difficultly attacked by such agencies Among the latter class may be recounted the lignocelluloses, the true celluloses, the cuto celluloses, especially the leaf cuticles, spore and pollen exines, the resins and the waxes It has been found that the coals are composed in a large proportion, if not entirely, of this class

The lignites are composed approximately of from 75 to 85 per cent of stems, branches and twigs, almost entirely of coniferous origin, in a very much vertically compressed and changed condition, the interstices being filled in with a plant refuse, analogous to a recent black peat, in which resins, pollen exines, spore exines, cuticles and waxes form an important part These constituting a crystalloid component are imbedded in a colloidal substance, mainly a derivative of cellulose Here as in all the coals, nothing but the outer wall or

exine of the spore and pollen grains is now left, and of the leaves nothing but the cuticle, rarely the epidermis, is left.

The brown coals from Lester, Ark., are composed of a "débris" only, in which the crystalloid components form a very large proportion, fern spore exines also are very abundant. To these constituents must be ascribed the oil yielding properties of this coal.

In the bituminous coal from Exeter, Ill., the "wood" is represented mainly by thin, jetty, black, lamina, between which is found a component closely resembling the débris of the younger coals, having as a ground substance a much macerated woody or colloidal material in which a greater proportion of crystalloid substances are imbedded. All the elements found in the younger coals and also megaspores are represented. The bituminous coal from Shelbeyville is very similar but has a much greater proportion of crystalloid material, megaspore exines and cuticles.

The cannel coals examined are composed almost entirely of spore exines of a variety of forms, resins and cuticles are present only in a very subordinate amount. The so called binding matter in the interstices of the spore exines is distinctly composed of two kinds of substances, one more or less homogeneous, colloidal in nature, and the other more or less granular, the fragmentary residue of spore exines.

The algal theory of Bertrand and Renault, and the sapropellic theory of Pontonié were rejected as being undemonstrable in every particular. The bodies supposed to be algæ can be shown not to be algæ, and all but one kind have unmistakably been proved to be the exines of certain spores, either of Pteridophytes or Cycadofilicales or both. A gelosic substance, such as the algal theory calls for, is entirely absent.

W. W. Stockberger,
Corresponding Secretary

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

At the 452d meeting of the board of managers, held March 23, 1911, the following resolutions submitted by the undersigned committee were adopted by the board and ordered published in Science.

"Acting on the information furnished by one of its members, Dr. Aleš Hrdlička, in regard to the wholesale destruction of antiquities in all parts of Peru, as well as in other regions of South America, the Anthropological Society of Washington has, after due consideration, resolved that

"1. The remains of American aborigines, wherever met with, and particularly in such countries as Peru, where native civilization reached high standards, are historical records of definite branches of the human family and, as such, are of great value to science, to the country in which they exist and to mankind in general.

"2. In view of such value of the remains in question, which include all manifestations of human activity, and also the associated skeletal parts of man himself, the destruction of these records is deprecated and the hope is expressed that scientific men and societies, as well as the proper authorities, will counteract the same as far as possible."

W. H. Holmes,
A. Hrdlička,
Walter Hough,
Committee
I. M. Cassanowicz,
Secretary

THE AMERICAN PHILOSOPHICAL SOCIETY

Dr. F. M. Jaeger, professor of inorganic and physical chemistry and head of the department of chemistry in the University of Groningen, Holland, gave an illustrated lecture "On Fluid Crystals and Anisotropic Liquids" before the American Philosophical Society on March 3. He explained why this question was one of the most ardently discussed problems of physical chemistry at present, how the old conception as to the molecular movement of the liquid state can not hold in the face of the newly discovered facts. He pointed out the close analogy between these phenomena and the polymorphic changes of matter and discussed the properties of substances melting successively to two, three or more liquid states. He demonstrated the principal physical properties of the above substances, their birefringence, magnetic induction, surface-tension and circular polarization. He discussed the so called "emulsion theory" and proved its valuelessness for the explanation of the different phenomena.

In short, it is proved now undoubtedly that liquids can share the characteristic properties of crystalline matter and that they display phenomena which indicate a regular molecular movement in the liquid state. The whole subject is of the highest importance both for physics and for chemistry.

THE ORIGIN OF THE THERMAL WATERS IN THE YELLOWSTONE NATIONAL PARK[1]

INTRODUCTION

FROM the earliest days of systematic geological research thermal springs have been a frequent subject of investigations by students of natural phenomena. From time to time numerous contributions to scientific literature bearing upon the nature of hot springs, partly descriptive and in part theoretical, have been presented to learned societies. Nearly all regions where such waters issue from the ground on an imposing scale appear to have been at one time or another scenes of eruptive energy. In so many instances has this been shown to be the case that thermal activity and volcanic manifestation have come to be regarded as associated phenomena. It by no means follows, however, that the original source of all these waters was, geologically speaking, deep-seated, and by a large school of geologists it has never been so regarded. In recent years the results of several suggestive researches have been published, in which the position is taken that superheated waters from igneous rocks are primitive in their origin, that is to say, they are derived from great depths in the earth's crust and are brought to the surface for the first time by volcanic forces.

The Yellowstone National Park affords one of the most remarkable, and probably one of the most instructive areas of thermal springs and geysers to be found in the world. The varied phenomena of boiling springs and aqueous vapors there stand unsurpassed. Several years ago, after a

[1] Annual address of the president, before the Geological Society of America, December 27, 1910.

study of the region under the auspices of the United States Geological Survey, I published in official documents, and later in Johnson's "Universal Cyclopædia," an article entitled "Thermal Springs," in which I stated the conclusion that the waters of these hot springs and geysers were essentially meteoric waters that had penetrated downwards a sufficient distance to attain an increased temperature, only to be forced again to the surface by ascending currents.

I propose on this occasion to present briefly some of the geological evidence on which these conclusions are founded. They are based on the nature and structure of the rocks through which the heated waters reach the surface, the mineral constituents contained in the waters, the composition of the associated gases, and the characters of the varied sediments and incrustations deposited around the springs and pools.

EOCENE IGNEOUS ROCKS

To understand correctly the relations of the thermal waters found in the park to existing geological conditions, a brief history of the salient features of its igneous rocks and their sequence seems necessary. The country included within the Yellowstone Park, the Absaroka Range, and the Wind River Plateau, consists essentially of masses of igneous rocks covering an area of over 5,000 square miles in the center of a continent whose three great rivers, the Mississippi, the Colorado, and the Columbia, here find their source. Within this region, through that vast period of time from the close of the Archæan to the dawn of the Tertiary, all evidences of eruptive energy are wanting. Coincident with the earliest indications of the post-Laramie orogenic movement came a period of intrusion which began in late Cretaceous time and continued with only slight periods of rest till near the end of the Pliocene. Whatever the primary causes were that produced this orogenic movement, the enlargement of the continental area, and the final withdrawal of the sea, they brought about mountain uplifts, crustal displacements, and volcanic activities of the first magnitude. The close of the Cretaceous in this part of the northern Cordillera was marked by the most profound stratigraphic break since Algonkian time. The oldest intrusives, recognized as such, are found in the northwestern corner of the Yellowstone park in what is now the Gallatin Range, and inaugurated a physical revolution. These rocks were forced in as sills between upper Mesozoic sandstones before the latter were much disturbed, as they lie unconformably interbedded between sediments which later were affected by the dynamic processes of mountain elevation. In this sense these earliest intrusions must be considered, structurally at least, as of Cretaceous age. They were succeeded by more powerful injections, accompanied by slow and protracted elevation of the Gallatin Range. With the emergence of land surfaces erosion followed and sediments were deposited unconformably. Elevation of mountain masses produced new physiographic features, and as a consequence changes in climatic conditions and modifications of living species, both animal and vegetable. The Tertiary period was ushered in. With the progressive building up of the range and the associated folding and compression of strata, viscous magmas were injected from unknown depths. Massive bodies were forced upward to definite levels, when, being unable to rise higher, they spread out laterally between strata of all ages from the Cambrian to the Laramie. Centers of powerful intrusion shifted from one locality to another, and within the confined limits of the range batholiths of no

mean proportions were forced upward Evidence is wanting to show that any of these magmas in their upward movement ever penetrated to the surface, apparently they came to a standstill far below a covering of overlying sediments whose thickness must, for the present at least, remain a matter of conjecture Excessive erosion since early Eocene time has laid bare these massive batholithic forms which now stand out as dominant features in the landscape

There is no evidence to warrant the opinion that these porphyries and crystalline rocks were ever connected with vents discharging lavas, though there is, beyond the boundaries of the Gallatin Range, extravasated material of Eocene age covering large tracts of country In the northeast corner of the park such surface flows are well developed in the accumulation of silts and ashes Much of this material was laid down under relatively quiet conditions Apparently they are much later than the crystalline rocks already referred to, but their age is determined by a characteristic flora corresponding with the well-known Fort Union beds of Montana of Eocene age

In these extravasated lavas the influence of volcanic waters may be recognized in many ways, but degradation of the mass has been so great that evidence of individual extinct hot springs is no longer traceable, moreover, it would seem impossible to distinguish them from those belonging to Miocene eruptions

MIOCENE IGNEOUS ROCKS AND THERMAL WATERS

The Absaroka Range shuts in the park plateau along its eastern border Strictly speaking, it is not a mountain range, but rather a rugged, deeply dissected tableland, rising from 3,000 to 4,000 feet above the general level of the park It stretches for eighty miles in a north-and-south direction and measures nearly fifty miles in width In strong contrast to the Eocene igneous rocks this elevated tableland was steadily built up by tumultuous accumulations of breccias, agglomerates, silts and muds, the products of violent explosive action through numerous conduits from sources now concealed beneath the overlying load Nearly all phenomena of ejected lavas seen in extinct volcanic areas elsewhere may be observed here Finally, the mass was penetrated by batholithic intrusions, accompanied by innumerable dikes and sills, offshoots from the parent stock All this was the result of long-continued, protracted energy, as clearly shown both by geological processes and the many successive fossil forests These flourished through thousands of feet of eruptive material and were alternately killed by hot fragmentary lavas and preserved by renewed streams of muds and ashes[2] The luxuriant vegetation which developed throughout this period is regarded by all paleobotanists as of Miocene age All volcanic activity long since ceased

What concerns us most at the present time is the influence of thermal waters derived from deep-seated sub-crustal sources upon both the volcanic ejectamenta and crystalline intrusives The action of these heated waters may be observed equally well on what were surface flows and on the deeply buried intrusive masses Such surface action may be detected at a number of localities by the presence of alteration products and traces of sediments, although in most cases the latter have been removed by running water Underground action of sub-crustal waters is shown in many

[2] Arnold Hague, "Early Tertiary Volcanoes of the Absaroka Range," presidential address, Geol Soc of Wash, 1899, SCIENCE, March 24, 1899

places from one end of the range to the other by deposits laid down from ascending igneous emanations in the form of aqueous and gaseous vapors charged with mineral matter Such deposits consist essentially of quartz, galena, and copper minerals, carrying both gold and silver They lie as contact products along the apophyses of the massive intrusions and never occur far away from them They were deposited after the crystalline intrusives came to a state of rest, but probably long before they were chilled It may not be necessary to add, but it should be borne in mind, that at the time of deposition they were much farther below the surface than they are found to-day Mining companies have exploited the ores by shifts and tunnels, but so far as I know, such ore bodies have never proved lucrative, owing to their uncertainty and lack of continuity Similar ore bodies in the mining regions of Montana and Colorado have been described by Emmons, Lindgren, Weed, Kemp, and others

Another feature of these intrusive rocks of the Absarokas is seen in the narrow rifts and shrinkage cracks filled with quartz by the ascending currents from deep-seated sources In like manner the cavities and druses found in the petrified trees of the fossil forests are lined with quartz crystals, due to heated siliceous waters coming up from below To-day there are no hot springs or steam vents to be found in the Absarokas, save in a feeble way on the western flanks, where the ancient breccias have been penetrated by much later rhyolites

It has seemed necessary to present this somewhat lengthy description of volcanic forces existing in Miocene time in order to bring out in strong contrast the conditions prevailing during Pliocene and recent times

PLIOCENE IGNEOUS ROCKS AND THERMAL WATERS

After the pouring out of the basic breccias and lavas of the Miocene, volcanic energy, for a time at least, ceased Atmospheric agencies removed a large body of the surface rocks and carved out drainage channels in the easily disintegrated material Following a prolonged interval of comparative rest came renewed activity, with marked changes in the nature of the eruptive lavas Vast masses of rhyolite were extruded, not upon preexisting mountains, but over an enclosed basin, converting it into a rugged tableland and submerging the flanks of the bordering ranges This sharply defined region has been designated as the Park Plateau It embraces a tract of country fifty by forty miles, including approximately 2,000 square miles Strictly speaking, it is not a plateau in the general acceptation of the word, but presents a broken surface accentuated by bold escarpments and abrupt slopes of lava flows While the topography of the tableland has, to some extent, been modified since Pleistocene time and trenched by ice action, giving the effect of individual plateau blocks, the mass can not be considered otherwise than as a geological unit The earliest rhyolitic eruptions spread over a very uneven surface, the structural features of which may be fairly well inferred from exposures of sedimentary rocks rising through the surrounding lavas or cropping out from beneath the outer boundaries of the plateau The rhyolite also lies unconformably upon the eroded surfaces of basic breccias, and not infrequently occupies the older valley bottoms, clearly showing the much later age of the siliceous lavas Although sharply defined by topographic relief and geological sequence, both periods of ejection are still more strongly contrasted by marked dif-

ferences in the phases of eruption which built up the two volcanic regions

On the rhyolite plateau there are no evidences of violent explosive action The complete absence of true volcanic breccias is a significant feature of these later flows Dikes, veins and horizontal sills, together with nearly all the phenomena of deep-seated intrusions, are wanting The rhyolite shows scarcely any indications of hydrothermal activity during eruption In the abrupt escarpments made up of successive sheets there are no signs of surface flows having been exposed to long-continued atmospheric agencies, no wind-strewn ashes or any vestiges of vegetation On the contrary, everything clearly indicates a relatively rapid accumulation of viscous masses from the beginning to the end of the rhyolite period What impresses one most is the absence of stages of activity with intervals of quiescence, there being rather a series of massive eruptions piled up one upon another In the central portion of the park the rhyolites have a maximum thickness of 2,000 feet, and over large areas they may be assumed to measure 1,500 feet

Subsequent to the rhyolites and the building up of the park plateau came a few dikes and thin sheets of basalt They are the most easterly occurrence of those broad basaltic flows that spread over southern Idaho and the Snake River plain In the park country they are of Pliocene age, that is to say, they are older than the glacial ice They make the final chapter in the history of Tertiary igneous rocks As they play no recognized part in the problems bearing upon thermal waters they may be dismissed at the present time with this brief mention

Unquestionably the Pleistocene age, with its changed conditions, set in not long after the dying out of rhyolitic eruptions, as is shown by the relatively slight erosion of the plateau and the beginning of canyon sculpturing All geological evidence tends to prove that the rhyolites belong to the Pliocene age

DURATION OF THERMAL ACTIVITY

That the activity of thermal waters was approximately coincident with the cessation of rhyolite ejections is, fortunately, clearly proved by the massive horizontal beds of calcium carbonate laid down on the summit of Terrace Mountain, where they attain a maximum thickness of nearly 250 feet, although the average is much less Without doubt they are the oldest deposits of travertine in the region of Mammoth Hot Springs, and rest directly upon fresh, unaltered rhyolite Glacial ice from the Gallatin Mountains moving eastward occupied the intervening Swan Lake Valley and passed over the top of Terrace Mountain on its way to the broad, open valley of the Yellowstone On the recession of the glacier fragments of crystalline rocks, undoubtedly brought down from the Gallatin country, were left strewn over the travertine of Terrace Mountain

It is a fair assumption that if these thermal waters were issuing through rhyolite at one locality in pre-glacial time, similar hot waters and gaseous emanations should have reached the surface at other points on the plateau If any such remnants of sinters still remain it seems impossible, from our present knowledge, to discriminate between them and those of post-glacial time Erosion has carried away not only every trace of these earlier deposits, but has removed nearly all evidences of pre-glacial rock decomposition Modifications in topographical relief fail to indicate two distinct periods, owing probably to the relatively slight deposition of sinter before the ice

Following the withdrawal of a broad ice sheet, ascending heated waters, acting with renewed energy upon the walls of innumerable fissures and rifts, bleached and kaolinized massive blocks of rock. This decomposition of plateau lavas proceeded on a grand scale and left an indelible impression upon the rhyolite areas. In regard to the age of the hot springs it is reasonable to conclude that thermal waters were as active at the close of the rhyolite extrusions as at any subsequent period. The antiquity of many localities of decomposed rhyolite is clearly evident, as shown by post-glacial sculpturing. In certain areas where hydrothermal energy was formerly a long-continued process, evidence of the presence of such sources of heat have long since ceased. No one who has studied the gradual development of these decompositions and metasomatic changes under the influence of acid solfataras, or the deposition of sinter now taking place from alkaline siliceous waters, can doubt the lapse of time required by these geological agents to accomplish the results observed. Such processes can not, however, differ essentially other than in degree from those observed to-day. In my opinion, they have never ceased to be active and have only varied in intensity from time to time. It meets all the requirements, therefore, for our present purpose, to consider the phenomena now taking place or since the hot springs and geysers were first brought to the attention of the scientific world, about forty years ago.

CLIMATIC CONDITIONS

Precipitation of moisture over the plateau and encircling mountains is far heavier than that taking place over the semi-arid regions below. Not only is the rainfall higher for every month of the year, but the temperature is correspondingly lower. Four large rivers, the Yellowstone, Snake, Madison, and Gallatin, carry the waters from the uplands to the lowlands. Knowing the amount of water leaving the park by these principal drainage channels, it is easy to estimate approximately the total amount of surface waters carried away.

Meteorological records, more or less complete, have been kept at Mammoth Hot Springs for over a quarter of a century, and during one winter at the Firehole Basin. From these data an approximate estimate can be made of the water falling over the entire region. Some years ago instrumental measurements were undertaken during the summer to determine the amount of evaporation on the open sinter plain in the Upper Geyser Basin. Similar observations were made at the outlet of Yellowstone Lake. Taking into consideration the annual precipitation and run-off, and the summer evaporation, I believe the supply of water greatly exceeds the amount carried away by surface streams. Climatic conditions, as they exist in the park to-day, favor forest development and a varied undergrowth. It is estimated that over 82 per cent. of the region is forest-covered. For eight months precipitation occurs in the form of snow, which, protected by the forests from the sun's rays and the drying winds, melts slowly and lingers on well into midsummer. On the adjoining mountains the snow seldom entirely disappears. The retention of the water by forest and undergrowth brings about the development of the many meadows, marshes and bogs. Scattered over the tableland occur frequent ponds and lakelets, carrying in the aggregate a very considerable body of water. In this connection may be mentioned such large reservoirs as Yellowstone Lake, covering over 125 square miles of surface, and Sho-

shone Lake, measuring 12 square miles, to say nothing of other picturesque sheets of water of less imposing dimensions, all of which lie upon the rhyolite from 500 to 700 feet above the Upper Geyser Basin, where the greatest number of large geysers is found and the activity and overflow of thermal waters displayed on a grand scale. In time, much of the water from the meadows and ponds naturally finds its way to surface streams. Another portion is taken up by the luxuriant vegetation or is absorbed by the atmosphere. The remaining water, which constitutes a very considerable volume, is drawn down through openings into underground reservoirs. In other words, these descending waters slowly percolate through the viscous lavas.

PHYSICAL STRUCTURE OF RHYOLITES

Returning for a few brief moments to rhyolite flows, let us consider certain physical features due to textural modifications. No region surpasses the Yellowstone Park in the varied phenomena of highly acid extrusions. This is especially true of the more glassy types, and in general a glassy ground mass characterizes most of these lava sheets. Mr. J. P. Iddings has submitted a large series of specimens of the park rhyolites to a searching petrographical investigation, making a special study of the microgranular structure, and the relations of the different microstructures to one another, and pointing out the abrupt transitions from the glassy to the crystalline and from the pumiceous to lithoidal forms. For further details the student is referred to this admirable work. In conclusion, Mr. Iddings calls attention to the agency of water in bringing about the varied products. He says:

> The heterogeneity of the acid lavas so far as known is confined to the distribution of vapors, presumably of water, and suggests that the water thus irregularly disseminated has not existed within the magma long enough to become uniformly diffused. It must therefore be looked upon as water absorbed near the earth's surface.[8]

From the point of view of the present discussion the cause of these remarkable structural variations concerns us less than the influence exerted by such textural modifications in the creation of fissures, fractures and capillary openings for the percolation of waters. Obsidians, perlites, and pitch-stones were poured out over the greater part of the central plateau and may be found at the base of bold escarpments, under accumulation of successive flows. Glassy forms present as marked a feature of many of these earlier outpourings as they do of the more recent flows. They were surface flows when ejected. They prove conclusively, on geological evidence, that similar physical conditions were identical from the beginning to the close of the rhyolite phase of eruption. The liquidity of the magma and its crystallization changed from time to time, being dependent upon varying causes, such as the degree of temperature when ejected from the point of discharge, the volume of the mass, and the power of the lava to hold its contained heat.

Banded and laminated lavas, contact surfaces between magmas of different physical properties, shrinkage cracks and jointings in obsidian and perlite, overlapping of lava flows, all caused numerous narrow capillary spaces in the rock. Some of these openings for short distances lie parallel with the lava flows, others are vertical along planes of jointing, while still others indicate great irregularity, broadening and contracting along a circuitous course. Uniting below the surface, they develop into wider channels, affording free circu-

lation of either descending or ascending waters

MINERAL AND CHEMICAL COMPOSITION OF RHYOLITE

As I hope to be able to show that the mineral matter brought to the surface in solution by ascending thermal waters circulating through rhyolite is mainly derived from these lavas, it is necessary to examine in detail both their chemical and mineral composition The chemical composition of the rhyolite appears remarkably uniform when the enormous bulk is considered and the different physical conditions under which the lava streams were extravasated

In the subjoined table will be found analyses of eleven specimens of rhyolite, arranged according to their tenure of silica They were made in the laboratory of the United States Geological Survey, but are here brought together in tabular form ties, but, curiously, analysis fails to show the presence of both in the same flow Traces of manganese have been detected in many specimens from widely separated parts of the tableland, which is interesting from the fact that in one or two localities solfataras have deposited manganese oxide as dendritic incrustations Considering the rhyolite as a homogeneous mass the composition of the molten magma is probably best shown in the specimen from Madison Canyon Here the silica percentage was 75 2 per cent, the alumina 13 77, and the combined potash and soda 7 16

As regards mineral composition the rhyolite is by no means as simple, owing to textural modifications that range from semitransparent, amorphous obsidian, to liparite with relatively little ground mass Nevertheless, the species that have crystallized out from the magma are few in number, the only essential rock-making minerals being quartz and sanidine In certain lavas quartz, in irregular crystals, occurs abundantly disseminated as megascopic phenocrysts while in others it is wholly wanting Plagioclase stands next in order, being easily recognized in many thin sections under the microscope, although being seldom recognized by the naked eye This is probably owing to the small amount of alkaline earths present Small flakes of biotite have been detected here and there, but in the typical rhyolite

In five analyses the range in silica falls within seven tenths of a per cent Lime and magnesia show the greatest variation, while the alkalies do not appear to be higher than in many other localities where rhyolite has been extravasated in the form of massive eruptions Titanic oxide has been determined in small amounts, but was not detected in the obsidians or in any of the extreme glassy rocks On the other hand, both sulphuric acid and chlorine occur in small quantities in the fresh glassy varieties, but, curiously, analysis fails to show the presence of both in the same flow

it may be said to be absent Pyroxenic minerals are rare and only in microscopic crystals Magnetite is somewhat more widely distributed, but only in minute grains, as might be supposed from the low percentage of iron oxides The presence of titanium in the magma reveals itself in the disseminated grains of ilmenite and pseudobrookite Apatite, zircon, and allanite complete the limited list of accessory minerals

CLASSIFICATION AND COMPOSITION OF THERMAL SPRINGS

The number of springs scattered over the park, from which flow varying amounts of thermal waters, probably exceed twenty-five hundred If to these be added the fumaroles, solfataras, and narrow rifts from which issue steam and gaseous emanations mingled with more or less water, the number would be greatly augmented It is impossible to enumerate them, as new ones are frequently reaching the surface, while others are slowly becoming extinct Furthermore, it would be no easy task to decide whether single points of discharge should be counted, or considered as a group having a common source a short distance below ground These thermal waters reach the surface holding mineral matter in solution, derived from the decomposition of rocks through which they pass in their upward movement They may be arranged under four heads (1) waters carrying calcic carbonate in solution, (2) siliceous alkaline waters rich in dissolved silica, (3) calcic siliceous waters having both properties of calcic carbonate and siliceous alkaline springs, (4) siliceous acid waters, usually holding free acid in solution

Nearly thirty of these thermal waters have been analyzed by F E Gooch and J E Whitfield in the laboratory of the United States Geological Survey and the results published in a separate bulletin[4]

Among these waters are several from the Mammoth Hot Springs characterized by the large amount of calcic carbonate in solution, associated with free carbon dioxide and sulphates of magnesium and the alkalies Underground conditions were doubtless favorable for holding in solution large amounts of calcic carbonate With the relief of pressure at the surface and the diffusion of free carbon dioxide, precipitation followed, as shown in the deposits which have made the Mammoth Hot Springs so famous From the present point of view we are not so much concerned with depositions from these waters as with the waters themselves and their geological relations, since they unquestionably have a common source with those of the rhyolite plateau

At the Mammoth Hot Springs the upper lava flows lie directly against inclined Jurassic limestones The circulating hot waters having been diverted in their course, traverse the limestone before issuing at the surface Apparently the waters derive a large part of their mineral constituents from the limestone In contrast to the hot waters of the plateaus they carry but little silica in solution Far to the southward, where the rhyolite tableland ends, the attenuated lava streams also rest against uplifted limestones Calcic carbonate springs, although of modest dimension, issue through the rhyolite, but have derived their mineral contents mainly from the adjacent limestones Both the carbonated waters and the travertine deposits resemble those at Mammoth Hot Springs Similar geological relations may be observed near the eastern

[4] F A Gooch and J E Whitfield, "Analyses of Waters of Yellowstone National Park," Bull U S Geol Survey No 47, Washington

limits of the rhyolite at Soda Butte Spring, and again near the western border

On the other hand, wherever the heated waters issue from the rhyolite of the tableland they are characterized by a high percentage of silica These waters occur distributed over a wide area and furnish the great volume of water discharged from the geysers and hot springs, and for this reason have excited more general interest than the smaller springs They have supplied the silica for the many square miles of glittering white sinter plains For the most part they are siliceous alkaline waters, as in the Upper Geyser Basin and the Firehole Basin They may, however, be slightly acid or neutral, as in the case of many of them in Norris Basin

The silica occurs in solution as hydrated silica associated with carbonates and chlorides of the alkalies, together with small quantities of sulphates Arsenic and boron have been determined in nearly all geyser waters, probably combined with soda as arsenates and borates Traces of bromine, phosphoric acid, soda, manganese, lithium, cæsium and rubidium were detected in several instances, but lithium and bromine are the only elements present in sufficient quantities to allow of estimation Tests were made for titanic acid, nitric acid, iodine, fluorine, barium, and strontium, but none of them were found Special examinations were made in concentrated solution for tin, copper, and lead, but no one of them was present In this connection it may be pointed out that while veins carrying lead, copper, and silver are found associated with Eocene and Miocene igneous rocks, these metals have never been detected in either the rhyolite or waters of the park

A study of these chemical analyses brings out clearly the marked differences in percentages of substances held in solution, especially silica, even in adjoining geysers. This holds equally well for the siliceous alkaline waters from the same geyser basin as from those collected from different localities Waters examined the same year show as great variations as those collected one or two years apart The silica, as determined by analysis, ranges from 22 to 67 gram per kilogram of water, the former being the amount found in the cauldron of the Excelsior, having the largest outflow of any pool in the park, and the latter from Opal Spring in Norris Basin, with but slight run-off, and without any apparent inflow The cause of these differences is, I believe, to be sought in the varying amounts of infiltrating surface water

Dr W H Hallock has shown conclusively, by experimental tests with self-registering thermometers, that the thermal waters stored in underground geyser reservoirs possess a temperature far in excess of the boiling point at the surface, due to increased pressure of the overlying column of water in the geyser tube The results were in accord with the theoretical boiling point It can not be affirmed positively that these superheated waters maintain the same composition after being thrown out as the underground waters at greater or less depth or even with those of the geyser reservoirs On the other hand, there exists no evidence of chemical changes due to relief of pressure before the waters reach the surface through geyser orifices

Upon the relief of pressure, hydrated silica, associated with traces of an equally insoluble silicate of alumina and lime, is deposited upon the broad plains of the geyser basins Nearly all remaining constituents are carried away in solution by surface streams Although the composi-

tion of the deposited sediment is everywhere much the same, its external habit varies with the manner of its secretion, which may have happened in several ways It may have been caused by precipitation on relief of pressure, precipitation on cooling, separation by evaporation, and assimilation by algæ Mr Walter H Weed has shown conclusively the important part such organisms perform as geological agents in the accumulation of sinter deposits [5]

The volume of siliceous alkaline waters far exceeds those of the acid type On the other hand, the latter occur more widely distributed, are more complex in their composition, and consequently more varied in their deposits These acid waters come to the surface through fumaroles, solfataras, and the so-called mud springs and paint pots In nearly all such occurrences the waters carry either free hydrochloric or sulphuric acid In general these thermal waters, which rise through narrow seams and rifts, run but little water and leave behind only thin incrustations around the sources of supply These deposits are found widespread over the park and consist principally of sulphates of alumina and double compounds of alumina and iron While they show a mingling of saline compounds carrying more or less silica as an impurity, the number of mineral species remains singularly few Halotrichite, alunogen, and alum are the only minerals of the alum group determined In the far more arid regions of New Mexico accumulations of these minerals have been described by Dr C W. Hayes[6] as deposits from aqueous solutions associated with igneous rocks

Under quite different conditions, and as thin layers deposited below water level in the Norris Basin, occur incrustations of both sulphides of arsenic—orpiment and realgar They are, however, very restricted in quantity Scorodite, delicate crystals of sulphur, and ochreous deposits, mainly ferric oxide and silica, are characteristic of certain acid and neutral waters These sediments and incrustations point clearly to different conditions of thermal activity In strong contrast from those described in connection with siliceous alkaline waters they indicate an earlier stage in the development of rock decomposition

GASES FROM THERMAL SPRINGS

Several years ago gases emitted from many of the springs were collected and submitted to analysis by Professor F C Phillips of Pittsburgh They were all found to carry carbon dioxide, oxygen, hydrogen, and nitrogen but to vary greatly in relative amounts In general, those from Mammoth Hot Springs, where the waters issue through limestones, are characterized by carbon dioxide, one analysis from the spring upon the main terrace holding no less than 98 68 per cent of the gas Those from the upper basin, which issue directly from the rhyolite, consist principally of nitrogen, the Artemesia Geyser carrying 95 08 per cent of the latter gas Traces of methane were found in several waters Hydrogen sulphide was only detected in two samples, and in neither of these did the gas amount to one per cent of the gaseous content One of these was from a sulphur spring in the Mammoth Hot Spring Basin, and the other from the Shoshone Geyser Basin In none of the waters from the geysers and large hot

[5] Walter H Weed, "Formation of Travertine and Siliceous Sinter by the Vegetation of Hot Springs," U S Geol Survey, Ninth Ann Rept, Washington, 1890

[6] Dr C W Hayes, Bull U S Geol Survey, No 315, pp 215–223, 1906

springs in the three principal geyser basins was any hydrogen sulphide detected

Professor Phillips says

> There is, in fact, a curious gradation between analyses from No 1 and No 10, as regards the proportion of nitrogen and carbon dioxide Oxygen is present in all of them, and as ten of these gases contain combustible elements, hydrogen and methane, it is evident that the gas as it escapes from the spring has not been exposed to a high temperature

It is admitted by most authors that under certain conditions all these gases may be contained in surface waters I think it has been shown that under the peculiar conditions in which these waters occur, and their lack of uniformity of composition, they must be considered as absorbed by vadose waters

One of the most marked characteristics and one of geological significance is the frequent variation shown in temperature, flow, and salinity of the thermal waters where they issue from the rhyolite plateau The solvent power of water holding mineral matter in solution is, as is well known, far greater than that of pure water Now the downward percolating waters gather material from the disintegrated rhyolite soil and in some measure from the soluble salts previously brought up from below There is also a certain amount of carbon dioxide derived from the atmosphere It is a fair assumption, therefore, that in percolating downwards the waters carry with them to the water level below no inconsiderable amount of material

The ascending superheated waters, under pressure, exert a far greater influence The work done by these waters, and that which is still going on, is self-evident even to the most casual tourist It is shown by the broad areas and ridges of altered and bleached rhyolite Nowhere is this more in evidence than in the escarpments along the Grand Canyon of the Yellowstone, where the gorgeous coloring is due to the oxidation of the ferruginous minerals The potent influence of such waters under existing conditions can hardly be questioned They readily attack both the glassy groundmass and crystalline feldspars of the rhyolite, and when the metasomatic changes are complete they leave behind an impure kaolinized material mixed with quartz and held together by colloidal silica

DEVELOPMENT OF SPRINGS AND GEYSERS

The ascending waters, in their circuitous course, penetrate fresh seams and cracks in unaltered rock which slowly widen under the disintegrating influences of aqueous vapors Finally, the thermal waters, following these cracks, issue at the surface as hot springs and pools The early waters are usually acid in composition, and deposit ferric and aluminous salts Occasionally they set free sulphur, derived from the decomposition of hydrogen sulphide In time the openings through which they flow become broader, the waters themselves, free from hydrogen sulphide, become clearer and neutral, and at last issue as siliceous alkaline waters Underground reservoirs are excavated and become sources of hot springs, and, under favorable conditions, geysers The geyser itself is simply a stage in the development of geological processes In time geysers themselves become extinct New geysers break out and, given the essential physical conditions, may develop eruptions quite as fine as any in action at the present time Geologically speaking, the final stage of thermal activity is a hot spring The tendency of a geyser is to develop a hot surface pool If from such pools there is discharged a sufficient amount of overflow, and if from the surface of these geyser pools there is an ample dissipation of heat into the surrounding atmosphere, explosive

action may cease and the geyser, as such, may become extinct. It is frequently stated that some geyser has ceased to be active and that this indicates the slow dissipation of the original source of heat. This I believe to be an error. The change is simply due to a shifting of the channel of the ascending waters.

If, on the other hand, there should be marked climatic changes and arid conditions should set in over the park and adjoining mountains, in my opinion, thermal springs would become extinct. Should this happen it would be evident beyond all question that the waters were derived from vadose sources. Again, with the disintegration of lavas and the building up and enlargement of reservoirs, existing conditions of hydrostatic pressure would cease and the circulating waters, unable to rise, would distribute themselves laterally, in which case there might break out at the base of the rhyolite plateau calcic springs such as we now find and have already described.

In all probability the magnitude of a geyser is, in a measure, dependent upon the size of the underground reservoir or series of reservoirs, produced by the disintegration of lavas along channels of ascending waters. It has been demonstrated by self-registering thermometers that cool infiltrating waters may drain into partially erupted reservoirs after geyser eruption. This has been shown in the case of the Giantess Geyser. The question was once asked by an attendant at the hotel who had spent several summers in the park, why Old Faithful was more apt to be several minutes behind time in September than in July. I am not aware that such a condition was ever established, but if so, my reply would be that in the autumn the infiltration of surface waters is not as rapid as in early summer, hence a retarding of the eruption by several minutes.

It is probable that the Norris Geyser Basin, in its thermal development, is later than the Upper Geyser Basin. In the former are found the early and more acid conditions, the waters of the geysers are mainly neutral and form deposits of arsenical sulphides, alum, and ferric salts. These phenomena are for the most part absent in the Upper Geyser Basin, where the waters have reached a more advanced stage and possess a siliceous alkaline composition.

With the exception of arsenic and boron, which occur in minute quantities, all the elements brought to the surface in solution by the thermal waters of the park have been found in the rhyolite. In this connection it may be said, and it is generally accepted by those who have studied the region, that the mineral waters of Pfaeffers, in the Tyrol, have a vadose origin, and analyses show that both these elements are present.[7] Both these elements are found associated together in many thermal waters of Europe. Not only is it true that, with these exceptions, all the elements are accounted for in the rocks, but the proportion of the ingredients in the waters bears a remarkable relation to that of the elements in the rhyolite itself. Silica and the alkalies are the predominating elements. Even lithia, which is a feature of many siliceous lavas, has been quantitatively estimated in all these thermal waters. The water from Old Faithful yielded .0056 of a gram per kilogram of water, which, according to the theoretical composition, shows that lithium chloride forms 2.44 per cent. of the amount of material held in solution. The neighboring Giantess Geyser carried precisely the same amount of lithium chloride. The low percentage of iron, manganese, lime, and magnesia contained in the ascending waters is readily accounted for by the comparatively small

[7] M. De Launay, *Annales des Mines*, February, 1894.

quantities of these elements in the glassy rhyolite through which these waters pass.

The circulating ascending waters may, to some extent, be charged by foreign substances other than by superheated aqueous vapors. Nevertheless, in the park country the vadose ascending waters do not appear to have been greatly affected by any primitive, deep-seated waters or their contents. Even if foreign mineral matter were present, it does not follow that the material was not taken up originally by vadose waters.

In Iceland geological conditions are apparently quite different, and volcanic eruptions may be said, geologically speaking, to be still going on, in strong contrast to the Yellowstone Park, where such action ceased many thousand years ago. In Iceland the thermal waters are, in my opinion, mainly vadose, and their heat derived from sources not far below the surface.[8]

I agree with Dr. Rudolf Delkeskamp[9] that temperature, included gases, and salinity in many localities are not in themselves conclusive evidence of the source of thermal waters, and that far safer criteria for the determination of the primitive origin of waters are to be sought in uniformity of flow and chemical composition. What I wish to emphasize, however, is that the thermal waters of the Yellowstone National Park are characterized by frequent variations of temperature, progressive transitions in chemical composition, lack of uniformity in mode of occurrence, and shifting in points of discharge, in other words, they lack the essential characters of primitive waters derived from deep-seated sources.

RADIOACTIVITY OF THERMAL WATERS

Throughout this paper in the discussion of the geological relations of the thermal waters to the rhyolite eruptions laboratory investigations bearing upon the composition of the rocks, waters, sediments and gases have been utilized. In the discussion of the circulation of descending and ascending waters almost nothing has been said in relation to the source of heat which raised the temperature of these waters. This is in part due to the fact that the problems involved are in great measure distinct from those treated here and time does not permit of their consideration, and in part because I know little about the matter. My opinions are still open to conviction. With this avowal I may be allowed to add that I am reluctant to believe that the source of the heated waters is, geologically speaking, deep-seated or sub-crustal.

In this connection it might not be out of place to mention the investigations of Professor Herman Schlundt and R. B. Moore, on the radioactivity of the thermal waters of Yellowstone National Park, conducted under the auspices of the U. S. Geological Survey, and recently published.[10] They found the rhyolites, limestones, thermal waters, gases, and sediments to be radioactive. Specimens of rhyolite from widely separated localities in the park were examined. These authors say:

> These data certainly seem to indicate that the hydrothermal activity so manifest in the park is

[8] Since presenting this address I have received from Dr. Thorkell Thorkelsson, of Copenhagen, a copy of a suggestive paper on "The Hot Springs of Iceland" which confirms me in the opinion of the vadose origin of the Iceland thermal waters. Dr. Thorkell's paper appears as a recent publication forming one of the *Memoires de l'Académie Royale des Sciences et des Lettres de Danemark*, Copenhague, 1910.

[9] "Juvenile und vadose quellen," *Balneologischen Zeitung*, XVI., Jahrgang, No. 5, 1905.

[10] "The Radioactivity of the Thermal Waters of the Yellowstone National Park," U. S. Geol. Survey Bull., No. 395, 1909.

not connected with localized deposits of radium In the above calculations the question of heat lost by diffusion and other factors is not taken into consideration, but after allowing a generous margin for error we do not see how more than one per cent of the heat required for the hydrothermal action can be ascribed to the radium content of the rocks

Recently deposited travertine at the Mammoth Hot Springs, as well as that of the Main Terrace, and from the preglacial capping on Terrace Mountain, was subjected to similar tests The same authors say

The travertine of Terrace Mountain is overlain by glacial boulders Since its activity is only one per cent of the recent deposits its age is about 20,000 years, which would also be the approximate time that has elapsed since the glacial period in the park

Furthermore, a sample of the Jurassic limestone underlying the Mammoth Hot Springs proved to be more radioactive than the most active sedimentary rocks tested by that eminent authority, R J Strutt, of England It is noteworthy that the latter rocks referred to were specimens of the oolite formation from near the celebrated springs of Bath

Strutt has also pointed out that siliceous igneous rocks are more radioactive than basic lavas,[11] a highly significant observation when it is borne in mind that the rhyolite of the Yellowstone National Park stands preeminent as an acid, crystalline rock Iddings and Cross[12] have shown that allanite, in microscopic crystals, is widely but sparsely distributed in the siliceous igneous rocks of the Rocky Mountains, and has been detected in the rhyolite of Yellowstone National Park Now allanite is known to carry small quantities of thorium It is a coincidence worthy of note that thorium emanation was determined in several of the hot pools, it being first observed in this country in thermal waters in an obscure hot spring in Norris Basin I see no reason, however, to doubt the conclusions of Messrs Schlundt and Moore that the heat produced by radioactive emanations from the rocks and waters is wholly inadequate to meet the requirements It seems necessary, at least from our present knowledge, to look elsewhere for the source of the heat dissipated by the thermal waters of the Yellowstone Park

SUMMARY

In conclusion I may state that I have attempted to show (1) that igneous activity was continued throughout Tertiary time, (2) that this activity came to an end with the close of Pliocene time, (3) that during the Eocene and Miocene deep-seated waters were active geological agents, and that these waters were essentially primitive in their origin, (4) that in strong contrast to the explosive, volcanic conditions of the Miocene, the Pliocene lavas were emitted under far quieter conditions and built up the successive flows that formed the rhyolite plateau, (5) that during the many thousand years since the withdrawal of glacial ice, the Pliocene rhyolites have, since the beginning of Pleistocene time, been steadily undergoing progressive changes, brought about by the action of enormous volumes of superheated vadose waters, (6) that the gases contained in the thermal waters were in great measure derived from vadose sources, (7) that the eruptions and periodicity of geysers are phenomena due essentially to varying conditions of reservoirs and channels of superheated waters situated only short distances below the surface, (8) that the

phenomena, as seen to-day, represent a phase in the evolution of thermal springs

ARNOLD HAGUE

U S GEOLOGICAL SURVEY

HISTORIOMETRY AS AN EXACT SCIENCE

IN the issue of SCIENCE for November 19, 1909, under the title "A New Name for a New Science" I proposed the term historiometry for that class of researches in which the facts of history have been subjected to statistical treatment according to some method of measurement more or less objective or impersonal in its nature These researches have chiefly had in view the listing and grading of historical characters, either for the purpose of studying mental heredity or for the better appreciation of problems associated with the psychology of genius Researches of this type are capable of a far greater expansion and application than is generally supposed They can be applied to events as well as to individuals They can, by treating the vast store of human records which exist in books as material for the construction of an exact science, work towards the solution of a wide range of historical problems, such as the causes underlying the rise and fall of nations or other fundamental questions in history

Before anything can be done which shall give general satisfaction and agreement it will be necessary for this subdivision of science to justify itself, to measure its own shortcomings, to appreciate its own limitations, as well as to prove its own right to recognition of independent estate

If we are to fathom historical causation by objective methods it is obligatory first to prove that history itself, as we commonly find it in the printed records, is a sufficiently valid account of what actually happened Second, it is equally necessary to find proof that the objective methods correctly deal with these facts It might be supposed that the second proof awaits the first, but this is not necessarily so If the records themselves were very much at fault, so that the statements of historians were very far from ideal truth, or if the objective methods of collecting and analyzing these statements were subject to a large error (or if both these forces were in play) then it would be difficult to find wherein the trouble lay But if, on the contrary, it fortunately be that history as we find it is in its important statements a fair representation of the truth, and if the methods of historiometry which deal with these records are also sound, then it is not difficult to prove both propositions at the same time

I will give some instances to illustrate this, which show that such is the case for several types of historical records and for several methods of history measurement This could not be done did we not possess some third criterion, some third standard of comparison of a non-historical nature One such non-historical criterion is furnished by the known correlation ratios for resemblances between close blood relatives as determined in the anthropometric laboratory. These have been worked out and accurately measured for mental and moral traits, stature, head index and length of forearm I have shown in "Heredity in Royalty"[1] that if the members of royal families are graded by the adjectives applied to them by historians and encyclopædists and then the coefficients of resemblance are measured between the near of kin, who have been so graded, these coefficients (historiometric) substantially agree with the anthropometric Such would not be the case if historians perverted the truth greatly, or if for any other reason the truth were largely unattainable To make this clear it is only necessary to think what the result would be if history were merely "a pack of lies agreed upon" as the extreme view puts it We should then fail to properly pick out our true intellectual giants and runts The result would be nothing but confusion A whole series of errors would be distributed at random This would act like rain on waves and flatten down to a common level the real differences between the individuals The correlation measurements would fail and we should get no results comparable to those obtained from the delicate and ac-

[1] New York, Henry Holt, 1906

curate measurements of the anthropometric laboratory.

Furthermore, any weakness in the method of grading, any failure to properly classify the great men in the high grades and the degenerates in their proper grades would work in precisely the same direction to lower the correlation coefficients. The supposed errors of history and the difficulties of grading act as two united strains of tension to pull the coefficients down towards zero, which would be the coefficient for random distribution. If the coefficient can stand the strain without declining, then, roughly speaking, we may conclude both that the historical foundation is just and that the method of procedure is sound.

There are two other illustrations of method which I would like to summarize here. One of these series of tests is the trying out of a standard biographical dictionary (historical persons) against two lists of contemporaries (non-historical persons) and all three in terms of still another set of facts, namely birthplaces of distinguished Americans. The second series of tests concerns the relative fame of Euripides *versus* Sophocles, the encyclopædias having been used and then this compared with expert modern criticism and both with the opinions of the Athenians.

As concerns American history, one fact is very evident at the start: whatever be the method of grading as applied to Americans or whatever be the mental eminence graded, some states in the union, some sections of the country, have produced more eminence than others far beyond the expectation from their respective white populations. In this regard Massachusetts always leads, and Connecticut is always second, and certain southern states are always behind, and fail to render their expected quota. I have already pointed out[8] that the ratios seem orderly for a first approximation. That is, the higher the grade of the individuals the greater and greater becomes the proportion of those born in Massachusetts. This may be expressed as a ratio, ρ into the random expectation. Thus if there were no forces at work beyond chance distribution the ratios for all sections of the country would be expressed by unity, $\rho = 1$. If there be found twice as many persons born in a certain locality as one would expect from the population let it be expressed as $\rho = 2$, three times as many, $\rho = 3$, etc. These ratios are easily computed and can be expressed as fractions or with decimals. I have computed these ratios for the thirteen original states, but will present here only the statistics from Massachusetts and Virginia.

It will be seen in Table I. that Massachusetts has never failed to produce twice as many eminent men as the population would lead one to expect, and has for some ranks and types of achievement produced about four times the expectation. ρ ranges between 2.1 and 4.7. Virginia, on the contrary, has but rarely produced as many as might be expected from the large white population and the ratios in the same table are either below the expectation or not significantly above it. The other New England states (statistics not here given) have all done more than their share, but always less than Massachusetts. New York gives a trivial though constant excess above the expectation. From here southward the ratios drop off suddenly, so that New Jersey, Delaware, Pennsylvania, Maryland, North Carolina and Georgia have always furnished less than their share. For South Carolina the ratios again rise and exceed the expectation but only by the slightest measurable amount. North Carolina, of all the thirteen original states, has always had the worst record in the way of producing distinguished men, the ratios falling to about one quarter of what might be expected from the white population.

Regarding the tables for the two contrasted states, Massachusetts and Virginia, and following down through the columns marked "ratios, or number of times the random expectation according to the population at the approximate age of their birth," one sees first that the Massachusetts ratios run from 2.1 to 3.9 and the Virginia from 0.2 to 1.1. The higher Massachusetts ratios are associated

[8] "American Men of Science and the Question of Heredity," SCIENCE, N. S., Vol. XXX., No. 763, pp. 205–210, October 13, 1909.

with the lists of names in which the standards for admission to the lists are higher—that is, specially selected groups of the more eminent. Massachusetts also shows an extra merit when science or literature is alone considered, but this is merely an accentuation of some cause or causes which have enabled her to lead, no matter what type of success be the criterion.

There is also to be seen a probably significant gain in the ratios for Massachusetts from the census of 1790 to 1850. A further study of this special phenomenon might develop some interesting conclusions. The ratio also rises when only those in *Lippincott's* are considered who have received adjectives of praise. Nine tenths of the persons named in this dictionary are given a passing notice by the editors and nothing critical is said of their lives or their work beyond the barest record. About one tenth receive such adjectives of praise as "celebrated," "illustrious," "eminent," "famous," "noted," etc.

A priori we may suppose that these represent an extra superior group as compared with the other nine tenths. *A posteriori* the supposition is verified, because how else can be explained the rise in the ratio for Massachusetts from 2.8 to 3.8? If this "adjective method" did not select a superior group it would not raise the ratios, or in other words draw it further away from random hazard for which $\rho = 1$. The more accurately it seizes hold of the right persons and justly expresses real differences dependent upon natural causes the more it will raise this ratio. One can now see how it is possible in this way, and in similar ways, to actually test the validity of any method of selection. Its value depends, among other things, upon its ability to raise, or lower, a ratio in a proper degree, suitable to the case in hand, so that the ratios shall fit in, and harmonize with other ratios and other results.

If, for instance, the "space method," or the selecting the 234 men who have had the most space allotted to them in the dictionary, had not raised the Massachusetts ratio from 2.8 to any more than say 2.9 or 3.0 we might be justified in concluding that this method was inferior in accuracy to the "adjective method." As it turns out, it raises the ratio to 3.6. So one suspects that the "space method" is not quite as accurate as the "adjective method," since it does not raise the ratio as much though it deals with a smaller group. Of course one instance like this does not decide anything. I merely give it as an illustration of the ways in which historiometry may proceed.

I have also essayed a new method, namely selecting from *Lippincott's* a list composed of all those Americans whose biographies have been written and published in separate works. This constitutes a very small and presumably correspondingly select group, 129 in number. The ratio for Massachusetts is here seen to rise to 3.9, practically the maximum. It should of course do so if the method is sound and is successful in seizing hold of the right men. This may prove a very accurate, practical and rapid method of objectively listing great men in ancient or modern history, subject of course to such limitations and adjustments as special problems may require.

It can be seen that the general raising of the ratios is in no way dependent on the dictionary containing a large number of clergymen and writers. As a matter of fact, more than a third of the names are those of lawyers, bankers, merchants, politicians, government officials, soldiers, manufacturers and engineers. Here by narrowing the list from 1,266 to 232 and dealing with only a small group, we raise the ratio from 2.4 to 3. It might be supposed by some that a greater attention is shown Massachusetts by writers of books, biographies and histories because these writers live in the neighborhood. "Lippincott's Biographical Dictionary," however, is published in Philadelphia. Still it may be influenced by previous writings and earlier biographical dictionaries published in the neighborhood of Boston. If this is so to any appreciable extent then we should expect the ratio for Massachusetts to fall when present-day persons are graded by methods which have either nothing or little to do with historical traditions.

TABLE I

List of Names	Total in the List Born in U. S. A.	Number Born in Massachusetts	Number Born in Virginia	Ratios, or Number of Times the Random Expectation According to the Population at the Time of their Birth: Mass.	Virginia
Lippincott's "Biographical Dictionary," edition of 1895	3,227	711	231	$\rho = 2.8$	$\rho = .6$
Same dictionary					
Americans born A. D. 1785–A. D. 1794	302	75	22	$\rho = 2.1$	$\rho = .6$
Born A. D. 1795–A. D. 1804	370	79	25	$\rho = 2.2$	$\rho = .6$
Born A. D. 1805–A. D. 1814	464	96	23	$\rho = 2.6$	$\rho = .5$
Born A. D. 1815–A. D. 1824	513	97	33	$\rho = 2.9$	$\rho = .8$
Born A. D. 1825–A. D. 1834	363	74	19	$\rho = 3.6$	$\rho = .8$
Born A. D. 1835–A. D. 1854	343	58	15	$\rho = 3.5$	$\rho = .6$
Average of the above six lists	2,355	479	137	$\rho = 2.8$	$\rho = .65$
Same dictionary, Americans who have received any adjectives of praise	320	95	23	$\rho = 3.8$	$\rho = .6$
Same dictionary, Americans who have been allotted extra space (20 lines)	234	67	20	$\rho = 3.6$	$\rho = .8$
Same dictionary, Americans about whom books have been written	129	39	14	$\rho = 3.9$	$\rho = .9$
Same dictionary, practical types only. Bankers, merchants, lawyers, politicians, government officials, engineers, manufacturers, soldiers	1,266	235	143	$\rho = 3.4$	$\rho = 1.03$
Same dictionary, selected list of the greater among the practical types (Adjective, space and biographical method combined)	232	60	29	$\rho = 3.0$	$\rho = 1.1$
"Who's Who in America," edition 1908–09	14,227	1,650	493	$\rho = 2.6$	$\rho = .9$
"Who's Who in America," practical types only (initials A–C)	1,131	132	33	$\rho = 2.5$	$\rho = .8$
"Who's Who in America," lawyers, judges, congressmen, government officials (initials A–C)	580	60	23	$\rho = 2.2$	$\rho = .9$
"Who's Who in America," engineers, inventors, architects (A–C)	134	16	3	$\rho = 2.5$	$\rho = .5$
"Who's Who in America," army and navy (A–C)	170	18	5	$\rho = 2.5$	$\rho = .7$
"Who's Who in America," business men, financiers, railway officials, manufacturers (A–C)	247	38	2	$\rho = 3.2$	$\rho = .2$
"American Men of Science," 1906, all persons	about 4,000	436	not yet calculated	$\rho = 2.7$	
"American Men of Science," 1906, the leading thousand	867	134	14	$\rho = 3.4$	$\rho = .4$
"American Men of Science," 1910, the leading thousand	874	131	17	$\rho = 3.4$	$\rho = .5$
Hall of fame (list slightly extended as in SCIENCE, N. S., Vol. XXXII., No. 813, p. 158)	50	20	7	$\rho = 3.3$	$\rho = .9$

Two such methods of grading we fortunately possess in the compilations known as "Who's Who in America," and "American Men of Science." The ratios for Massachusetts do not fall. They dove-tail in with the ratios from *Lippincott's*. Hence we may conclude that the differentiations found in *Lippincott's* are not caused by unjust historical tradition and, furthermore, as far as one can see they are not in part caused by the same. "Who's Who in America" has been often used as an objective basis for sociological inquiries, but the criticism has been made that this book gives undue inclusion of authors and professors. I think this criticism is unjust. About forty per cent. of the whole fall under the more practical types enumerated in Table I. These I have considered separately as far as the initials A, B and C. They yield a ratio for Massachusetts of $\rho = 2.5$, which is very close to that for the whole book $\rho = 2.6$. The same for *Lippincott's* is $\rho = 2.4$, which is not in its exact theoretical position, as it should be higher than that drawn from "Who's Who in America." It will, of course, be appreciated that the clearing up of small disagreements like this requires further analysis and the computation of the probable errors.

The ratios from Virginia I present in this abstract merely as a general contrast to Massa-

chusetts I prefer to make further statistical inquiries before attempting to interpret their meaning

The third series of tests which illustrate the exactitude of historiometry are drawn from comparative studies of the fame of Euripides and Sophocles In SCIENCE, October 7, 1910, Mr C A Browne called attention to the fact that Sophocles received the first prize from the Athenians twenty times, and Euripides only four times, while since their deaths various writers from Plato to Emerson have referred to and quoted Euripides more than Sophocles Mr Browne also shows that both Curtius and Grote, and biographical dictionaries, and encyclopedias as well, allot more space to Euripides than they do to his elder rival This seems to indicate that the opinion of the Athenians has been reversed by posterity, but the real explanation I have found to be otherwise

It appears that the problem that Mr Browne proposes is a very delicate one These two great Greek dramatists stand in such an exalted position and so close to one another, both being near the extreme range of human genius, that probably not two hundred individuals who have ever lived have exceeded them in eminence[8] Therefore, compared with all men of all historical time, these two are almost merged in something like a point at the extreme end of a line It is like splitting and measuring the components of a binary star at a great distance It would be no discredit to any objective method of differentiation if it failed to give interpretable conclusions As it is, it turns out that the problem presented is just within the limits of historiometric discrimination so that the figures yield uniformity and repetition warranting real conclusions

I have extended Mr Browne's list and have found confirmation of the statement that more space is devoted to Euripides than to Sophocles This would leave the impression that Euripides is to-day frankly considered the greater of the two, which is not the impression that one gains by even a cursory reading of the printed matter so spaced Furthermore, I am informed by John Williams White, Professor of Greek, Emeritus in Harvard University, that for the last hundred years the general estimate of scholars has placed Sophocles above Euripides This is precisely the conclusion which is obtained from the extraordinary character of some of the terms and sentences of eulogism which one finds applied to Sophocles In these same authorities one never finds for Euripides anything like the following "There has hardly been any poet whose works can be compared with those of Sophocles for the universality and durability of their moral significance of all poets of antiquity Sophocles has penetrated most deeply into the recesses of the human heart" (Muller and Donaldson) "He renders tragedy a perfect work of ideal art" (R C. Jebb). Occasionally the direct comparison is

[8] Conf J McK Cattell, *The Popular Science Monthly*, February, 1903, p 359

made and then Euripides suffers, for instance, as when Gilbert Murray says

> No wonder Sophocles won four times as many prizes as Euripedes . . . Sophocles shows at times one high power which but few of the world's poets share with him . . . in the second Œdipus there is a certain depth of calm feeling unfettered by any movement of mere intellect, which at times makes the subtlest and boldest work of Euripides seem "young man's poetry" by comparison

It can be easily seen that this general impression can be checked up and is unfailingly expressed by each ratio of the adjectives of praise (pro) against those of dispraise (con) For every single authority consulted the answer is the same,—the proportionate ratio favors Sophocles[4]

The "space method" fails here to give a verdict agreeing with modern and ancient opinion probably for special reasons peculiar to the case More plays of Euripides are extant and there is more to be said in the way of adverse or qualifying criticism It is not to be denied that the interest in Euripides is and always has been, intense, perhaps greater than in Sophocles, but the position of the latter is more majestic and more sublime The lexicons alone would have given this conclusion in a few minutes reading All these facts, in connection with those taken from Lippincott's dictionary, indicate that the "adjective method" is a very delicate way of measuring small differences if for any reason it is desirable to do so

The questions here touched upon concern only the individuals, but I know from material as yet unpublished that the quantitative objective method can be applied to events as well as to persons If its validity for the study of individuals can be securely grounded, then its application to events will naturally follow and will be thereby the more easily and surely established

Space has permitted only a brief abstract, but I think that enough has been given to prove that researches of this nature furnish harmony and order, intertwine and mutually support each other, form an organic structure, and are entitled to recognition among the exact sciences It must be remembered that exactitude in science is a relative term Abstract mathematics may be exact, but no science of physical measurement is really exact Astronomy, which is usually thought of in this way, only gives an approach towards an ever-expanding ideal No two observers have ever quite agreed upon the latitude of the Greenwich observatory and the last transit of Venus was, if I remember rightly, in comparison with the computed prediction, some eleven seconds off All we ask is that the exactitude shall be sufficient for the practical needs of the problem in hand

I think it must be agreed that this first synthesis and coordination of isolated researches presents a very encouraging picture It indeed gives proof that a workable instrument has been obtained capable not only of dealing with questions as intricate as human nature and its attributes but actually at the same time demonstrating the essential validity of the historical data on which are based the percentile grades, ratios, correlations or other super-structure This latter conception is to me the most interesting side of the whole matter It has usually been impossible to scientifically refute those critics who claim that the so-called facts of history are so uncertain and subject to so great an error and prejudice that it is unsafe to build conclusions upon them by statistical methods They have not of course ever known that such was the case nor have they ever had any way of estimating how far the records of history, as they exist in standard works, encyclopedias and biographical dictionaries, actually deviate from the absolute truth It has been assumed, on the other hand, by those who have been engaged in grading historical characters, that the records represent a fair approximation towards the ideal truth The human record which we call history stands somewhere between two extremes, somewhere between the quagmire of complete falsehood and heights of perfect truth It is possible as we go on to appreciate, with closer and

[4] In this part of the work I have had the assistance of Mr A A Jenkins, of the Harvard Law School

closer accuracy, just what deviation from ideal truth any great set of historical records contains.

Such researches give promise of at last furnishing the long-sought correct method of penetrating the tangled and perplexing jungle known as philosophy of history. This domain of thought is to-day in poor esteem among those who, as historians of the modern school, seek in documentary sources to reconstruct the past around some central theme, some individual age or nation. No wonder these careful investigators have become disgusted with the *a priori* dogmatism, the partizan spirit, the free generalizations from half truths and the eternally conflicting conclusions. Historical philosophers, in their desire to explain everything at once, have been content to formulate theories and then pick from the totality of history, selected facts to support them. With methods highly subjective, and carrying a large personal equation they could not help but find exactly what they wished. The ways of inductive science may be slow at first, but even a small nucleus of collected and coordinated facts soon grows with astonishing rapidity, and every objectively established piece of work makes it, with accelerated speed that much easier to progress along lines of certainty and exactitude.

SCIENTIFIC NOTES AND NEWS

LORD CURZON will succeed Major Leonard Darwin as president of the Royal Geographical Society.

THE Bessemer gold medal of the Iron and Steel Institute, London, will, this year, be awarded to Professor Henri Le Chatelier, the French metallurgist. The Andrew Carnegie gold medal for 1910 will be awarded to M. Félix Robin, of Paris.

A COMPLIMENTARY dinner was given on March 29 by former students of King's College Hospital to Sir David Ferrier, M.D., F.R.S., to congratulate him on receiving the honor of knighthood.

DR. LUCIUS L. HUBBARD has been appointed regent of the University of Michigan. He has been instructor in mineralogy at the State Mining School at Houghton, Mich., and was state geologist from 1893 to 1899.

MR. GEORGE HENRY LIVENS, B.A., has been elected to a fellowship at Jesus College, Cambridge. His subject is mathematics.

DR. EDNA CARTER, instructor in physics at Vassar College, has been awarded the Sarah Berliner research fellowship for women. She will continue her work in physics at Cambridge under Professor J. J. Thomson, and in the laboratory of Professor Wein, of Wurzburg, where she received her doctorate.

THE annual awards of the Royal Geographical Society are announced as follows: The two royal medals have been awarded, the Founder's to Colonel P. K. Kozloff, and the Patron's to Dr. J. Charcot. The Victoria Research Medal has been given to Captain H. G. Lyons, the Murchison Bequest to Dr. Wilfred Grenfell, the Gill Memorial to Captain G. E. Leachman (Royal Sussex Regiment), the Back Bequest to Dr. Arthur Neve, and the Cuthbert Peek Fund to Mr. R. L. Reid.

DR. H. F. MOORE, of the U. S. Bureau of Fisheries, has sailed for Rome where he will represent the Bureau at the fifth International Fishery Congress to be held May 26–31. Before returning he will visit the coast of Algiers for an examination of the sponge fisheries.

AN expedition under Mr. Homer B. Dill, of the State University of Iowa, has left San Francisco for Laysan Islands in order to study the bird life and bring back specimens for an extensive group to be placed in the museum.

PROFESSOR F. E. LLOYD, of the Alabama Polytechnic Institute, is planning a trip into the Arizona Desert this summer, in order to continue his botanical researches in desert plant life.

ACCORDING to the *Bulletin* of the American Mathematical Society, Professors E. R. Hedrick, of the University of Missouri, and J. I. Hutchinson, of Cornell University, have been

granted leave of absence during the second half of the present academic year, they will spend most of their time in Paris Professors E. J Wilczynski, of the University of Chicago, and C L. Bouton and J L Love, of Harvard University, are also spending the present half-year abroad on leaves of absence

PROFESSOR HAROLD B SMITH, director of the department of electrical engineering at the Worcester Polytechnic Institute, lectured before the Cornell branch of the American Institute of Electrical Engineers on March 31 His subject was "Some Engineering Developments of the Electric Field of Force"

ON April 5, 1911, the University of Pennsylvania Chapter of the Society of the Sigma Xi initiated sixty-eight new members Thirty-three of them are alumni of the university who graduated before the organization of the chapter and have since attained prominence in scientific work Eleven are members of the faculty and twenty-four are undergraduates The address to the initiates on "The Two Fields of Activity of the Learned Professions," was made by Professor I J Schwatt, president of the chapter, and the society was addressed by Professor Allen J Smith, dean of the medical department, on the subject, "Schools of Applied Science in Relation to the Graduate School"

MR HENRY A PURDIE, of Boston, one of the founders of the American Ornithologists' Union and long identified with the ornithology and botany of New England, died at the Massachusetts General Hospital on March 29 and was buried at Mt Auburn Cemetery, Cambridge, April 1

MR BERNARD AMEND, president of the firm of Eimer & Amend, and a former student of von Liebig, died in New York City on April 6, at the age of ninety years

ALPHONSE LOUIS PINART, a French traveler and philologist, died at Boulogne (Seine) on February 13, at the age of fifty-nine years

THE biological laboratory of the United States Bureau of Fisheries at Woods Hole, Mass., will open early in the coming June, for the twenty-seventh season since its establishment in the present quarters A limited number of research rooms and tables will, as usual, be placed at the disposal of those qualified to conduct investigations in the various branches of marine biology Applications should be sent at an early date either to the commissioner of fisheries, Washington, D C, or to the director of the laboratory, Woods Hole, Mass

THE twentieth session of the Marine Biological Laboratory of Stanford University will begin Wednesday, May 31, 1911 The regular course of instruction will continue six weeks, closing July 11 Investigators and students working without instruction may make arrangements to continue their work through the summer The laboratory will be under the general supervision of Professor F M McFarland, instructor in charge

THE Society of College Teachers of Education has entered into an agreement with the University Press of Chicago whereby the editorial management of the *School Review* will henceforth be under the control of an editorial committee elected by the society This editorial committee consists of Professor M V O'Shea, president of the society and chairman of the department of education, of the University of Wisconsin, Professor E O Holland, secretary of the society and professor of education in the University of Indiana, Professor William C Bagley, director of the school of education, University of Illinois, Professor Frederick E Bolton, director of the school of education, University of Iowa, and Professor Paul H Hanus, head of the department of education, Harvard University To this editorial committee representing the Society of College Teachers of Education has been added Professor Willard C Gore, Professor Frank N Freeman and Professor Franklin W Johnson, all of the faculty of the school of education of the University of Chicago Professor Gore has been elected by the committee managing editor of the *Review* As a result of this agreement, the *School Review* will become the organ of the Society of College Teachers of Education It is

planned to make it of service to all who are concerned in any way with secondary education in this country. It has been decided also to publish in connection with the *Review* a series of supplementary monographs dealing in a detailed and scientific way with problems of secondary education.

In the examination for resident engineer, Department of the New York State Engineer, the time for receiving applications has been extended to April 20, 1911, and the requirements for admission amended as given below. Resident engineer, Department of State Engineer and Surveyor, salary $2,400 to $3,000. Applicants must have at least five years' practical experience in civil engineering, three years of which must have been in responsible charge of work. Graduation from an engineering school of recognized standing will be accepted in lieu of one year of the five years' experience demanded. While candidates will not be assembled for a written examination, they may be summoned for an interview with the examiners. Subjects of examination and relative weights: Experience, education and personal qualifications, to be rated upon the candidates' detailed statements and upon answers to inquiries which the commission may direct to previous employers and others acquainted with their experience and qualifications and upon the oral examination, 1, two theses—a report upon some work of importance carried out under the charge of the candidate, and a discussion of some assigned topic relating to the problems to be handled in the construction of the barge canal, 1. The theses are to be written and submitted by the candidate in accordance with instructions to be issued by the commission, of which due notice will be sent to those who file applications. Non-residents will be admitted, subject to the provisions of civil service regulation X, that in case the eligible list contains the names of three or more citizen residents of New York state, they shall be preferred in certification over non-residents.

The summer field session for 1911 of the School of American Archeology of the Archeological Institute of America, will be held at El Rito de los Frijoles, near Santa Fé, New Mexico. Facilities will be given students to observe or to participate in the excavations, begun in 1908, and now in progress at Tyuonyi, near-by talus pueblos and cliff-dwellings. Excursions will be made to facilitate a study of botanical and other environmental conditions of the tribes dwelling in the vicinity. During August, lectures will be given on the distribution and culture of the tribes in the southwestern section of the United States, on the evolution of design as shown in ancient Pueblo art, on the native languages, and methods of recording them. A course will be given by Dr. Lewis B. Paton, formerly director of the American School in Jerusalem of the Archeological Institute of America, on "The Ancient Semites" to afford an opportunity of a comparative study of cultures developed in semi-arid regions in the eastern and in the western continents. Other lectures for comparative studies are being arranged for. The object of the annual summer field session of the School of American Archeology is to bring together persons interested in the study of anthropology, for first-hand investigation and discussion, and to give students the opportunity for field work needed to supplement university instruction. The attention of teachers and students engaged in the scientific study of education is also called to the advantages of this work. At the close of the session opportunity will be given to visit the pueblos of Taos and Acoma, and the government excavations among the cliff-dwellings in the Mesa Verde National Park, Colorado. For details of the summer session, address *Director of the School of American Archeology*, Santa Fé, New Mexico.

The sundry civil bill passed March 4, 1911, by the late congress provided for a reorganization and expansion of the Alaskan interests of the U. S. Bureau of Fisheries. A new division of the bureau is created, the Alaska Fisheries Service, to hold the affairs of the fur-seal, salmon and other fisheries, and of the fur-bearing animals. The latter field is an entirely new extension of federal super-

vision, under the act of April 21, 1910, vesting control in the hands of the secretary of commerce and labor The fur-seal and salmon fisheries have been for years under federal control, and are now taken out of the division of scientific inquiry, unifying under one head the whole Alaskan service The new division has a total personnel of 25 persons and an annual salary appropriation of $41,530 Of the personnel, eleven positions are new ones and consist of the chief an assistant chief, three clerks, one assistant salmon agent, one warden and four deputy wardens The increases apply mainly to the fur-bearing animals and the salmon fisheries, the fur-seal service having received in the year preceding additions to its personnel, made necessary by the expiration of the lease of the Pribilofs and the taking over by the government of the entire business of taking and selling seal-skins The chief of the Alaska Fisheries Service will be Dr Barton W Evermann, for eight years chief of the Division of Scientific Inquiry Dr H F Moore, for eight years principal scientific assistant in the Division of Scientific Inquiry, succeeds Dr Evermann as chief of that division Mr M C Marsh remains as chief Alaska salmon agent and Mr Walter I Lembkey as chief fur-seal agent

UNIVERSITY AND EDUCATIONAL NEWS

THROOP POLYTECHNIC INSTITUTE, Pasadena, Cal, has received for endowment four gifts aggregating a quarter of a million dollars. The largest is $150,000, there is one of $50,000, and there are two of $25,000 each The income becomes available after July 1, 1911

MR. JAMES A PATTEN has added $50,000 to the $200,000 which he had given to the Northwestern Medical School for the study of tuberculosis

A BUREAU of research in municipal government is to be established at Harvard University, to be maintained by a gift of $2,500 a year for ten years offered by Mr Frank Graham Thomson, of the class of 1897, and Mr Clarke Thomson, of the class of 1899, both of Philadelphia, Pa Professor W B Munro is to direct the work of the bureau In connection with this bureau material bearing on national and state government is to be collected, the work to be maintained by an anonymous gift of $1 000 a year for five years, Dr Arthur N Holcombe, instructor in government, is to be in charge

MISS MARY ANNE EWART has bequeathed £20,000 to Newnham College, Cambridge, for scholarships for women students and £10,000 to Somerville College, Oxford, for like purposes

NORTHWESTERN UNIVERSITY has arranged an architectural competition for the development of the university campus It is proposed to erect at once dormitories costing $150,000 and in the near future an academic building costing about $180,000

THE upper wall of the west tower of the William Rainey Harper Memorial Library, in course of construction at the University of Chicago, has fallen, demolishing the interior of the tower from top to bottom The loss, which falls on the contractors, is estimated at $50,000

PLANS for the first summer session of the Johns Hopkins University have been announced Work will begin on July 5 and will last six weeks

THE Nebraska legislature, reversing a previous vote, has permitted the University of Nebraska to apply for admission to the benefits of the Carnegie Foundation

BOWDOIN COLLEGE proposes to adopt a plan for admission to college similar to that of Harvard Students are required to present a record of their school studies and to pass an examination in four subjects only.

DR L H MURLIN, president of Baker University, has accepted the presidency of Boston University

MR WILLIAM J. DUPPERT, of the United States Forestry Service, has been appointed instructor in forestry at the University of Nebraska to take part of the work of the late Professor Frank J Phillips

MR. A. FRANKLIN SHULL, assistant in zoology in Columbia University, has been appointed acting assistant professor of zoology at the University of Michigan, to succeed Dr. A. S. Pearse, who has gone to the University of Manila.

MR. DUNHAM JACKSON, now studying at Gottingen on a Harvard traveling fellowship, has been appointed instructor in mathematics at Harvard University.

AT the Normal College, New York City, Charles T. Kirk, instructor, has been promoted to be assistant professor of geology, and Miss Emily O. Long, to be assistant professor of botany.

DISCUSSION AND CORRESPONDENCE

THE METHOD OF SCIENCE, A REPLY

A RECENT number of SCIENCE (January 27, 1911), has a forceful address by Dr. Minot on the "Method of Science." It is a new presentation of a topic fully discussed from the attitude of pre-evolutionary thought, but in such a manner and from such premises that its logic can not serve as a basis of present problems. I do not have the feeling of disrespect for the old thought that Dr. Minot seemingly has, but I agree with him that its principles and methods give little help in solving the problems science now faces. But at this point our differences begin, for in his restatement of principles, admirable as it is, he cuts the ground from under the social sciences by putting up standards that they can not meet. I do not think he meant to do this, yet the feeling he shows against the old philosophy warrants the inference that he would pass a similar judgment on the results of social science.

A new statement of the laws of thought is certainly needed. Early logic was devised by the theologians to prove the existence of supersensual units. As instruments for this end the so-called laws of thought are effective. But we need other rules to solve present problems. Not only is this so, but the methods of investigation have been so altered during the past fifty years as to create new problems. Accurate measurements are a new device. There were cases of accurate measurement before the present epoch, but they were not numerous enough to create a peculiar type of reasoning and thus to force a revision of the rules of logic.

The old division was between inductive and deductive logic. This controversy is now practically dead and in its place is arising one between inductions based on observation and those on experiment. Observations are generalizations under complex conditions, while experiment means isolation, simplicity of environment and accurate measurement. Workers in physical science distrust observations and demand in their place carefully verified results. This change is not a matter of theory, but due to practical situations faced by scientists in their various fields. The new medicine of which Dr. Minot is so good a representative gives an excellent illustration of the situation that forces him to attempt a reformulation of the laws of thought. The old practitioner was an observer; he diagnosed cases from symptoms. The new school experiments and measures. To say that science is exact measurement means practically to shut out the old physician who carried his knowledge in his head and whose office was not a chemical laboratory.

But if the laws of thought needed to shut diagnosis out of medicine are formulated as general laws, rules are set up that exclude all social judgments derived from observation. The tendency to do this is already visible in biologic sociology whose premises are taken bodily from biology. Bold deductions are made and conclusions drawn that sweep aside all generalizations based on observation. Here is a sample of reasoning of which we will have many more if Dr. Minot's rules of thinking win acceptance. I quote from a recent magazine article. "No generalization has ever exercised such a far-reaching effect on thought as the theory of natural selection. It is hardly necessary to point out that the corresponding belief in sociology is that all progress must come from the gifted individual, from the 'sport' who survives as the best of his kind. Darwinism lays stress not on the democratic

mass and their comfort, but on the few men of talent and their incomparable value to society" The essence of this position is the same as Dr Minot's[1] exact well-proven premises, a distrust of observation and the conviction that scientists seldom err except in their measurements This leads to long-range deductions and a neglect of verification within the field, where the conclusions are drawn

Such methods reflecting the growing tendency in science to disregard observation force those who use it to rise in its defence A controversy of this kind could not have arisen earlier because no one then questioned the validity of observation If, however, science has come to mean exact measurement and laws of thought are formulated in harmony with the new view, observation must also have its laws restated or its results will be questioned not in a few fields but in every part of scientific research.

When we seek to demark the field of observation from that of experiment, it will be seen that experiment is carried on under local specific conditions Only when an object is isolated and its environing conditions definitely fixed can the accurate measurements be made upon which the success of an experiment depends Observations, however, are made under complex conditions and usually they cover a large area of space or time The essence of an observation is to fix on some mark or characteristic of an object through which it may be recognized Reasoning through observation joins two such marks in the relation of cause and effect If "X" is always followed by "Y" the object of which "X" is a part is the cause of the object or event of which "Y" is a mark In observation wholes are thought of in terms of some of their definite marks and thus reasoning becomes a connecting of these marks in some casual relation In contrast to this procedure the "X" and the "Y" of an experiment are isolated from the wholes to which they ordinarily belong Then qualities and relations can thus be accurately measured and described

[1] I refer to such sentences as these "A broad examination of the method of science reduces itself to the study of the general principles of securing accuracy" "It must be doubted very seriously whether the study of logic is really essential for the right training of an investigator" "It is my belief that the logical work of scientific men is usually well done and is the part of their work which is the least faulty"

If this is the difference between observation and experiment, the mode of thinking used by the workers in the various sciences can also be contrasted There are four types of reasoning whose peculiarities depend upon the use made of observation and experiment The first group affirms that science is measurement and thus rules out observation This group of thinkers is of recent origin because the means of accurate measurement are a recent discovery It is no wonder that Dr Minot found books on logic useless for early logic gave rules for observation and deduction but did not recognize measurement as a means of investigation Now we have whole sciences within which measurement is the main source of progress whose workers are so effectively organized that observers of the older type are frowned down or excluded A social caste is thus formed who set up standards of their own and who issue a "Who is Who" of learned men from which they exclude those using observation as a method of research

The second method has become popular through the discussions of heredity that Dr Weismann began This assumes that if we have two series of events both measurable and certain the first is not only the cause but the sole cause of the second If, for example, there is a definite alteration of the hand it must have been caused by an antecedent modification of the germ cell of the organism All observations of the hand and all other sources of modification except those of germ-cells are shut out and a bold deduction is put in their place The method of this group thus includes nothing but measurement and bold unverifiable deductions They are playing havoc in the social sciences because their deductions become the basis of biologic sociology

If we pass from the sciences using experiment and measurement to the social sciences that depend on observation, we likewise find

two groups. The method of investigation correspondingly changes since social science can not readily get at causes by experiment but must begin with observation of results and work back towards causes by indirect methods. This method has lately been renamed pragmatism and involves a judgment of causes through their effects. Consequences are open to observation, causes are not. A cause must therefore be judged by its observed effects. The leading exponent of this method was the late Professor James. I do not wish to defend his arguments, but to call attention to his method. His observations—those on which truth depends—are psychic phenomena. We may therefore call this method psychic pragmatism, for the satisfaction that the perception of truth affords becomes its test. There is, however, another method that goes out from consequences just as Professor James does but which uses objective social tests instead of psychic tests. Social pragmatism uses marks to visualize wholes, but the marks are the objective social consequences of acts which can be measured and verified. Social consequences can be measured and through their observation a steady advance is possible in ways that will put social observation on a par with physical measurements as a means of developing science.

If it can be agreed upon that observation and experiment furnish the only basis upon which investigations can rest the next subject of importance is the canons of reasoning. Dr. Minot assumes that the reasoning of scientists is seldom defective and that their main errors are those of measurement. Scientists however, are as liable to errors of logic as other people and scientific method can not disregard the laws of thought. They are the very essence of good thinking and must therefore be formulated.

The first and primary rule is that only observations and experiments can be used as premises in deductions. This seems an innocent rule, but it involves more than at first sight is apparent. All experiments are local and specific in their conditions. There is no such thing as a general experiment and hence premises derived from them are local definite facts. The same is even more true of observations. They are made by individuals and no one can extend his observations over more than a local field. All valid data are therefore local and specific. Reasoning consists in extending the scope of these premises to other and broader fields. It follows from this that there is no difference in kind between an induction and a deduction. This distinction is due to the well-deserved disrepute into which the dogmatic assertions of theologians and metaphysicians fell. Scientists wanted therefore to get a peculiar mode of reasoning that would avoid these evils. In this they have failed. So many sciences have become deductive that the reasoning of scientists differ in no essential respect from that of any other group. The differences are in the premises and in the verifications, not in the reasoning. There is but one method of reasoning. Its rules apply to all thought and to all subjects. The same end that the distinction between inductive and deductive thought is attained by the second rule of good thinking. No generalization should be used as a premise in reasoning. A generalization is a result of previous thought and is only an approximate truth. Every new chain of reasoning must go back to the original data in the form of observations and experiments and be based on them together with the new data obtained since the original generalization was made. The chief violations of this rule are in social science, but scientists are not free from this error. They, like other people, form themselves into social groups and thus acquire dogmas and prejudices that induce them to use the generalizations of their group as premises when they should confine themselves to their data in the form of observations and experiments. Sound reasoning always goes from the local to the general. Universals are made either by some social group imputing value to a premise that serves their practical needs or they are loose generalizations based on imperfect data. Whatever their source, they are unsafe premises and lead to widespread popular errors.

From this it follows as a third canon of thought that all conclusions need an independent verification. If reasoning from generalizations were permissible and thought could legitimately move from an acknowledged universal to a particular, verifications would not be necessary. It is interesting to see the many ways in which thinkers try to avoid the need of verification. From this temptation scientists are no freer than other thinkers and they have furnished many notable examples of such errors. Verifications are, however, always necessary and they must be based on fresh data. Reasoning merely points out where these data exist and what data are pertinent. The work of getting at the truth is only half done when the conclusions drawn from premises are shown to be valid.

Thought is the connection between two objects or ideas brought about by the similarity or dissimilarity of their inherent elements. Progress in thought consists in passing from indefinite marks of this identity or difference to those capable of definite description and measurement. This fourth rule of good thinking brings out the relation between observation and measurement. Verifications are improved when observations are verified by experiment and experiment by observation. Only in this way can we be sure that the data of the verification are independent of those of the premises. There is a still further improvement when enunciated principles are based on observation and their verification consists of data arising from experiment and measurement. Such proofs are the most stable science can offer. It is a goal that can not always be reached, but it should always be striven for. Principles are most readily obtained from observation, their proof, however, is complete only when measurable data afford them a verification.

A final rule of thought is that no law is to be regarded general unless it is capable of independent statement and verification in many fields of investigation. This is the doctrine of multiple verification. It is often assumed that the way to prove a law is to get more data in some one field. Such a proof is less satisfactory than independent verifications coming from data derived from other sciences. It is the extension and restatements of a law in other fields and by independent investigators that raise its validity above local generalizations which have both time and space limitations. All observations and experiments are of this local character. They need multiple verifications to make them worthy of general acceptance. It is a corollary of this that thought is improved not by additional erudition in a given field, but by the movement of thinkers from field to field. There is a strong tendency to resent such a movement and the intruder is likely to receive rough treatment by his new colleagues. Yet this has been the way in which the greatest victories of thought are won. If Pasteur had not passed from chemistry to medicine his work might have been scientific, but it would not have been effective. Narrow specialization tends to such complete isolation of a group that its activity becomes socially valueless. The mobility of thinkers is the only safeguard against these evils. It makes trouble but it brings results.

Two conclusions follow from the preceding discussion. The first is that there is but one true method of reasoning in the use of which all are equally liable to error. The second is that there are two kinds of data, observations and experiments, both of which must form a part of any complete verification. These general statements would be of little use if they were not applied to the problems that separate social from physical science. While the opposition is general it is focused upon the controversies about man and his relations to the animal world. The one group use as their data the experimental knowledge of animals and then sweepingly apply this knowledge to man. "What is true of dogs is true of men" is a dictum coming from deductive medicine which illustrates the methods of all biologic sociologists. On the other side, there are social laws established by observation which have been accepted by the mass of mankind as rules of conduct. Which of these is right both in method and fact?

In the first place, it should be recognized

that men can not be put in laboratories and experimented on. It would seem, therefore, that observation must have a place in studies of man that it need not have in animal investigations. In the second place, the tests between the two methods do not lie in problems of normal development, but of pathology and degeneration. There are few observations about normality that are worth much. Social observations are mainly about defects and abnormalities. Keeping these facts in mind, the issue is clear. I will state it in the words of Dr. F. A. Woods: "Experimentally and statistically there is not a grain of proof that ordinarily environment can alter the salient mental and moral traits in any measurable degree from what they were predetermined to be through innate influences."[1] To test such a statement it must first be asked what are "mental and moral traits." If Dr. Woods means traits like sympathy, I agree with him. I know of no observational evidence showing it can be altered except by organic development. This may be true of all positive characters. But many so-called characters are not positive traits but merely conditions. We can not make good men better merely by an environmental change but we can in this way eliminate vice. Is there then a difference between a condition that leads to degeneration and a biologic trait that is necessary for progress? To be specific, are drunkenness, hysteria and criminal tendencies conditions having objective causes or are they biologic characters? Social observers point out what the conditions are that bring on these results and contend that the so-called traits appear and disappear with the presence or absence of given objective conditions. The deductive biologists start with premises about germ cells and apply their conclusions to man without verification. The difference is not one of fact, but of the sufficiency of bold reasoning.

If, as Dr. Minot asserts, scientists seldom err in conclusions when their measurements are exact the weight of authority is with theorists. I am not so sure of this as he is. The weakness seems to me to lie in the difference between the conditions of man's survival and those of lower animals. Before the rise of social sentiments elimination acted sharply against the defective individual, and hence degeneration could not become prominent. Then all traits were traits of survival and few pathological states appeared. Man, however, through sympathy preserves the weak and hence lowers the average man below his normal condition. If we regard one hundred points as the normal level in the animal world the lack of ten points would lead to elimination. In human society, however, a man could lack forty points and yet perpetuate his kind. I do not wish to attempt a mathematical demonstration, but it is plain that human sympathy reduces materially the sharpness of elimination. Sympathy could not act in this way if society did not have a surplus that it used to maintain the defectives. Sympathy is thus the indirect cause of the failure of elimination, but a condition of surplus is its direct cause. If it were absent, only normal people and normal traits would survive.

There are two objective conditions that reflect themselves in abnormal traits, a condition of surplus and a condition of deficit. The traits due to a surplus are usually called vices, while those of deficit are called crimes. These terms are not sharply contrasted, but their use is definite enough to illustrate my meaning. Give men more than they need and they sink into vice; take from them what they need and they become criminal. If vices and crimes can be changed or removed by altering income conditions we have proof that vicious and criminal traits are not biologic but economic in origin. We can then conclude that abnormal traits are not true biologic characters, but the impressment of economic conditions which are modified as the environment gives a surplus or deficit to those within it. A condition of deficit desocializes those who suffer from it and thus brings out atavistic traits not appearing in normal persons. A condition of surplus making people emotional, morbid and hysterical undermines the power of the will. Deficit people can be said to be

[1] *The Popular Science Monthly*, April, 1910.

too willful, while surplus people are almost will-less

I do not use this argument to show that my position is correct but to make clear what it is on which the contrasted arguments rest. The biologic sociologists are using bold deductive arguments without a verification. Their position has plausibility only by ignoring observational evidence. Deductive medicine with its neglect of diagnosis puts itself in the same position. The one group affirms that what is true of germ cells is true at maturity while the other says what is true of dogs holds for men. This is reasoning, not observation or experiment.

It is said of Agassiz that he took his students out to a great boulder near Cambridge and asked them what they saw on it. Some saw nothing; others saw vague scratches. Only he saw the ice-markings and proof that the boulder was deposited by a glacier. By the methods of to-day instead of these observations we would have exact measurements of the scratches; their depth and length would be carefully ascertained, and finally the Carnegie Institution would be asked to make a grant for weighing the stone. In this way note-books would be filled and a reputation made, but who will say all this is worth as much as what Agassiz saw with his unaided eye? Logic has pitfalls for all of us; we escape from our errors only by shrewd observations and multiple verifications.

S. M. PATTEN

UNIVERSITY OF PENNSYLVANIA

MIASTOR LARVÆ

THESE remarkably interesting larvæ, reproduced by pedogenesis, are available for laboratory work to a marked degree and must be widely distributed as well as allied forms. Very little is known concerning American species, largely because their habitat is one rarely explored by entomologists. They breed mostly in decaying vegetable matter. We have been very successful in finding them under partially decayed chestnut bark of stumps, fence rails and sleepers which have been cut one or two years earlier. European species have been observed under the bark of a variety of trees and even in sugar beet residue. These dipterous maggots with diverging antennæ have a flattened, triangular head quite different from the strongly convex, usually fuscous head of the *Sciara* larvæ occurring in a similar environment. They have a length of from one twentieth to one eighth of an inch and may be found in colonies containing a few large, white larvæ with numerous smaller, yellowish individuals, though the latter appear more common at the present time. Early spring with its abundance of moist bark appears to be the most favorable season for finding the larvæ. The writer would welcome the cooperation of entomologists and others in searching for these forms in different parts of the country. He will be pleased to determine specimens found under various conditions, make rearings therefrom if possible, and thus add to our knowledge of the subfamily Heteropezinæ, a group which should be fairly abundant in North America and one deserving careful study.

ALBANY, N. Y.

SCIENTIFIC BOOKS

Minéralogie de la France et des ses colonies, description physique et chimiques des minéraux, étude des conditions géologiques de leurs gisements. Par A. LACROIX. Paris, Librairie Polytechnique, Baudry et Cie, éditeurs. 1893–1910. Four volumes. 8vo. Pp. xx + 723, 804, vi + 815, iii + 923.

This monumental work, which testifies at once to the untiring industry of the writer and to his thorough mastery of the material he has collected, is destined to rank as one of the most valuable contributions to the science of descriptive mineralogy. It consists of four large volumes, containing in all about 3,300 pages, and illustrated with more than a thousand figures, a large number of which are photographic reproductions of characteristic specimens. The first volume was issued in 1893, and at that time the author believed that the work would be completed in two years' time by the issue of a second volume,

but the material was so abundant that the issue of a third, and finally of a fourth volume became requisite.

In his preface to the first volume M. Lacroix calls attention to the fact that France has been commonly regarded as a land poor in minerals, and he finds an explanation of this belief in the comparatively slight favor that has been accorded to mineralogical studies there. A careful consideration of the geological features of that land, the great development attained there by the crystalline schists, by the ancient eruptive rocks, and by the later volcanic ones, should have served as proof that a great variety of mineral forms would be found. The author has sought in every case to trace the mineral to its original source and, as far as possible, to study the conditions controlling its production.

While it is essentially a treatise of descriptive mineralogy that M. Lacroix has produced, he has sought to give, in the case of each mineral, all the information necessary for the student regarding composition, optical properties and general characteristics, so that there might be no necessity to have recourse to other manuals. The crystallographic data are given both in the notation of Lévy-Des Cloizeaux and in that of Miller, and this greatly facilitates the use of the book for those unfamiliar with the French notation. The measurements given are all from specimens secured in the French deposits, the greater part of which have been collected by the author himself.

The considerable interval of time intervening between the issue of the second, third and fourth volumes, and the accumulation of new data—especially from Madagascar—that the author has collected during the past decade, renders the last volume a supplementary one, but the various new items are always referred to their proper place in the general scheme of the work.

The rich material has been arranged, in the main, according to the classification of Groth, and the full and accurate index renders it an easy matter to find the information given in regard to each mineral. The small percentage of mineral substances not included in the work are those which have not been found in France or in her colonies. The number of gem-stones—that is, of stones furnishing gem-material—is comparatively small, except in the case of the Madagascar deposits. Of the precious metals also there is no great abundance, in spite of the well-known fact that in Roman times the Gauls were exceptionally well supplied with gold. They appear to have nearly exhausted the deposits with which they were acquainted, and no new ones of equal value have since been discovered. In this connection, we may note (Vol. II., p. 422) an illustration figuring a gold medal struck in 1786, and made from the first ingot secured from the mine of La Gardette, dept. Isère.

The fourth volume is largely occupied with the treatment of the great variety of minerals found in the French colony of Madagascar, many of these having been collected by M. Lacroix in 1902 and 1903, when he was on an official mission to the island. More especially the pegmatite rocks of Mt. Bity and its neighborhood have yielded fine specimens of a great many types and varieties with which we are already familiar, and also some that are new or have not been met with in the same perfection elsewhere. Among these may be noted a new species, bityite, named by M. Lacroix, and the beautiful pink variety of beryl, which the writer of the present review has named morganite, in honor of our distinguished fellow-citizen, J. Pierpont Morgan. As the beginning of the systematic search for minerals in Madagascar is of such recent date, we may hope that the future has other pleasant surprises in store for us.

In the course of the publication of this work, begun eighteen years ago, the author was elected a member of the Académie des Sciences in Paris, an honor no one has better deserved than he. His single-hearted devotion to the progress of science is well shown in the following words prefixed to the last volume of his book: "I shall consider myself amply rewarded for my long task if this book should help to stimulate the study of the natural history of minerals in France."

It must be welcome news to the French that their recent acquisition, Madagascar, known as the "Grande Ile," contains many minerals valuable from a commercial point of view, and which may eventually serve to make some return to France for her immense expenditure of blood and treasure in establishing her dominion in that island Very possibly similar investigations systematically conducted in parts of Cochin China and Tonquin would also reveal mineral deposits of value, not yet uncovered

M Lacroix, who was born in Mâcon, department Saône-et-Loire, February 4, 1863, was a pupil of F Fouqué, of Des Cloizeaux and of Michel-Lévy, and has been since 1893 professor of mineralogy at the Muséum d'Histoire Naturelle, in Paris, an institution founded in 1793, during the French Revolution Here the minerals contained in the Cabinet du Jardin du Roi, the greater part of which had been collected by D'Angiviller for Buffon, represent the nucleus of what has since become a most extensive and representative collection

The following illustrious men have served as directors of the museum Daubenton, 1793-1800, Dolomieu, 1800–1802, Hauy, 1802–1822, Alex Brongniart, 1822–1847, Dufrenoy 1847–1857, Delafosse, 1857–1876, Des Cloizeaux, 1876–1893, Lacroix, 1893 to the present time

The important collections forming part of the great museum collection[1] are as follows Collection de Chantilly (1793), Coll Weiss (1802), Coll Brongniart (1823), Cabinet de la Monnaie (Coll Sage 1825), Coll Gillet de Laumont, embracing the collection of Romé de l'Isle (1835), Coll Hauy (1848), Coll de l'Académie des Sciences (1855), Coll Dusgate (1874), Coll Bischoffsheim (1890). All of these, except that of Hauy and of M Bischoffsheim, are in the general collection

Besides his "Minéralogie de la France," M Lacroix has published an exhaustive study of the intrusions in volcanic rocks, and, in collaboration with M. Michel-Lévy, a study of the minerals characteristic of different rocks[2] In addition to these special works, no less than 260 articles and papers issued in various scientific journals bear witness to the great industry and to the many-sidedness of this writer[3] There is no broader mineralogist in Europe, the range of his knowledge and the extent of his work in geology, petrography, chemistry and crystallography, and in the correlation of these sciences, constitute and prove a combination of gifts and acquirements rarely met with in one man

The various scientific missions with whose execution M Lacroix has been entrusted have led him to Great Britain, Scandinavia, Italy, Germany, Greece, Asia Minor and Madagascar, as well as to North America and the Antilles After the dreadful eruption of Mt Pelee, he was selected to head the scientific expedition to Martinique in 1902–3. These missions have afforded him exceptional opportunities for the study of the conditions under which mineral forms appear in many different parts of the world, of their associations and probable genesis The wide experience thus acquired has undoubtedly contributed much to the special excellence of M Lacroix's work in the field of mineralogy Full appreciation has been accorded to him both in his native land and in foreign countries He has twice been Lauréat de l'Institut, in 1892, and in 1903, and, as we have noted, was elected a member of the Académie des Sciences, section of mineralogy, in 1904

He is an honorary or corresponding member of scientific societies in London, St Petersburg, Vienna, Rome, Turin, Kristiania, etc, and is also an honorary member of our New York Academy of Sciences

Eighteen names has Professor Lacroix added to mineralogy They are as follows Fouqueite (1889, *Bull Soc Min*, XII, 330),

[1] "Collection de Minéralogie du Muséum d'Histoire Naturelle," Deuxième édition, Paris, 8vo, 1900, 112 pp, 1 pl

[2] "Les enclaves des roches volcaniques," Mâcon, 1893, 770 pp with 35 figures and 8 colored plates, 8vo "Les minéraux des roches," Paris, 1888, 334 pp, 8vo

[3] "Notes sur les Travaux Scientifiques de M A Lacroix, Prof de Minéralogie du Muséum d'Histoire Naturelle," Paris, 1903, 4–126 pp

michellevyte (1889, *Comptes Rendus*, CVIII, 1128, "Minér de la France," IV, 48), morinite (1891, *Bull Soc Min*, XIV, 187, "Minér de la France," IV, 539) pseudoboleite (1895), gonnardite (1896, "Minér de la France," II, 279), ktypeite (1898), picrocrichtonite (1900, "Minér de la France," III, 284), pseudochalcedonite (1900, "Minér de la France," III, 159), grandidierite (1902, "Minér de la France," IV, 670), giorgiosite (1905), georgiadesite (1907), palmierite (1907), plancheite (1908, "Minér de la France," IV, 757), villiaumite (1908, "Minér de la France," IV, 881), bityite (1908, "Minér de la France," IV, 673), metacristobalite (1909, "Minér de la France," III, 806)

GEORGE F KUNZ

BOTANICAL NOTES

TWO NEW BOTANICAL JOURNALS

WITHIN the past few months two new botanical journals have appeared in this country, asking for recognition and support by botanists

The first in point of time is the *American Fern Journal*, the first number of which appeared about the middle of last August It is now announced to be the "official organ of the American Fern Society," and its place of publication is Port Richmond, N Y It is to be "devoted to the general study of ferns," and is to appear quarterly The field of the new journal appears to be distinctly systematic in the old sense, and would seem to be intended to serve old-time collectors of ferns, and the private makers of fern herbaria While the *Fern Journal* does not cover exactly the field already occupied by the *Fern Bulletin*, published by W N Clute, the latter being much less technical, it must be confessed that they are rather too nearly alike, and one is led to wonder whether there is room in this country for two journals devoted to such a small group of plants as the ferns However, we may hope that after a period characterized by a "struggle for existence" there may be a "survival of the fittest" In the meantime let us keep up our subscriptions for both periodicals, hoping that the best that there is in each may be preserved in the "survival," which may be a "Journal-Bulletin"

The other journal—*Phytopathology*—is also an "official organ," having for this relation the American Phytopathological Society It "is designed primarily as a channel of publication for the phytopathological contributions of the members of the society" The principal editors are Professor L R Jones, of the University of Wisconsin, Dr C L Shear, of the U S Department of Agriculture, and Professor H H Whetzel, of Cornell University It is to appear bimonthly, and the subscription price is three dollars

It is clearly to be a strictly scientific journal of plant pathology, having no popular leanings whatever Its field has hitherto been wholly unoccupied, and there should be no question as to the support of the journal It should be found on every botanist's table, and should be accessible to all students of plant pathology

A PERIODICAL FOR MOSS STUDENTS

A NEW chapter is opened for *The Bryologist*, with the January, 1911, number it becomes the property of The Sullivant Moss Society, and its officers recently elected become the advisory board President, Dr Alexander W Evans, Yale University, vice-president, Miss Caroline Coventry Haynes, Highlands, N J, secretary, Mr N L T Nelson, Des Moines College, Des Moines, Ia; treasurer, Mrs Annie Morrill Smith, Brooklyn, N Y They have appointed Dr A. J Grout, as editor-in-chief, with associate editors as follows Dr George N Best, Rosemont, N J, Dr. A W Evans, New Haven, Conn, John M Holzinger, Winona, Minn, and Professor Lincoln W. Riddle, Wellesley College, Wellesley, Mass

The Sullivant Moss Society has held seven most successful public meetings in affiliation with the American Association for the Advancement of Science, and plans to hold the eighth in the same connection at Washington, D C, this coming December.

It will be noticed that the associate editors represent an eminent authority in the several

groups treated of in *The Bryologist*, namely, Dr. Best, the pleurocarpous mosses; Professor Holzinger, the acrocarpous mosses; Dr. Evans, the Hepaticae, and Professor Riddle, the lichens.

HOUGH'S LEAF-KEY TO THE TREES

MR. ROMEYN B. HOUGH has brought out a handy pocket manual which he calls a "Leaf Key to the Trees of the Northern States and Canada." The booklet is of such dimensions that it can be carried very easily in one's pocket, its dimensions being 4½ by 6 inches, and not over a quarter of an inch in thickness. In about thirty pages all of the common native trees from the Rocky Mountains eastward, and north of the latitude of North Carolina, are briefly characterized by means of keys which refer principally to their leaves. With this in hand the tyro ought to find no difficulty in finding the name of any native tree in the region named. It should be especially helpful to young foresters.

SHORT NOTES

A YEAR or so ago W. N. Clute brought out a little "Laboratory Botany" (Ginn) for use in high schools, which should have been noticed long ago. It has already commended itself to teachers as a most useful laboratory guide.

THE crown-gall of plants is discussed very fully and conclusively in Bulletin 213 of the Bureau of Plant Industry, of the United States Department of Agriculture. The authors, Erwin F. Smith, Nellie A. Brown and C. O. Townsend, find that *Bacterium tumefaciens* produces tumors upon many species of plants in widely separate parts of the natural system. Thus peach, apple, rose, quince, chestnut, grape, etc., when attacked by this organism develop the growths known by the name of "crown gall."

Parts III. and IV. of Oakes Ames's "Orchidaceae" continue to maintain the high standard set in the first and second parts. The books are not only of high scientific value to the botanist, but the printing and paper are superb, and when added to the wealth of artistic etchings constitute volumes that any artist might be glad to own. They form a notable addition to the literature of botany.

THE POISONOUS EFFECTS OF ALCOHOLIC BEVERAGES NOT PROPORTIONAL TO THEIR ALCOHOLIC CONTENTS

SUCH a vast amount of investigation and discussion has been centered on the liquor problem during the last few years that it seems almost presumptuous to attempt to add any new information to the subject or even to emphasize a point which has been previously recognized but not thoroughly appreciated.

In the report of the investigations made by the sub-committee of the committee of fifty to investigate the liquor problem, Abel[1] states "That more concentrated alcoholic liquors or spirits are, from a practical point of view, the most toxic of all alcoholic beverages. If whiskey or cognac were always to be diluted with water until the percentage of alcohol was brought down to ten per cent. they would be no more toxic than wine of the same strength."

These statements would lead one to infer that if the alcoholic content of all beverages was reduced to the same percentage the toxicity of each beverage would be the same. If true, such a conclusion would greatly simplify the method of determining the relative harmfulness of the many kinds of alcoholic beverages.

Numerous investigators have subjected various living organisms to the influence of pure ethyl alcohol diluted with water and also to beverages which contained varying amounts of it. In general they have obtained definite results showing that alcohol in appreciable quantities is always injurious to living matter.

It is recognized that some species of living organisms are more resistant to the influence of alcohol than others, and also that some individuals of the same species are more resistant than other individuals, but if many indi-

[1] "Physiological Aspects of the Liquor Problem," 1903. A report by the sub-committee of the Committee of Fifty to investigate the liquor problem, edited by John S. Billings, New York.

viduals of any species are subjected to the influence of alcohol it can be determined in general how great an amount of alcohol the species can endure

In some experiments with rotifers, *Hydatina senta,* to determine the effect of different external influences upon the parent and offspring, various alcoholic beverages have been used and have given very definite results as to their relative toxicity These experiments are not exhaustive nor complete, but it seems advisable to record them since they demonstrate very clearly that the toxic effect of some of the common alcoholic liquors is not proportional to the amount of alcohol contained in them

The rotifers are microscopic aquatic animals living in certain kinds of foul water In the laboratory such water was prepared by placing a small amount of horse manure in a two-quart jar of tap water This mixture was inoculated with various kinds of bacteria and also with very small flagellated protozoa In about thirty-six hours the jar was swarming with millions of the small protozoa A cubic centimeter of this water containing the protozoa was added to nine cubic centimeters of tap water and then adult rotifers were placed in this mixture They lived in it readily eating the protozoa and laying eggs which developed into mature offspring in about forty-eight hours

Varying amounts of each alcoholic beverage were added to this water in which the rotifers lived thus causing the toxicity of the whole solution to vary according to the amount of the alcoholic beverage present in the mixture As an indicator to the toxicity of the beverages thus diluted with the water in which the rotifers lived, two points were noted (1) the percentage of alcohol present in the diluted beverage at which the animals died within 10 30 minutes, (2) the highest percentage of alcohol present in the diluted beverage at which the females produced apparently normal young

The following tables give the details of the experiments and bring out clearly the fact that alcohol is not the only cause of the injurious effects produced by alcohol beverages

If two beverages which contain approximately the same amount of alcohol are compared the poisonous effects of each are sometimes nearly equal as is true of claret and white wine or Holland gin and brandy, but, in other cases, the poisonous effects may be very unequal, as is very clearly shown in the comparison of the second sample of cider and Ballentine's ale Here the alcoholic contents of each are nearly equivalent but the toxicity of the cider far surpasses that of the ale in both sets of experiments as recorded in Tables I and II

TABLE I

Showing the Highest Percentage of Alcohol in the Beverages at which the Rotifers Lived 10–30 Minutes

Beverages	Per Cent Alcohol by Volume in Original Sample	Per Cent Alcohol in Diluted Portion of Sample Used	Duration of Life of Rotifers	No of Individuals Used
Cider	7 5	0 2	25 minutes	10
Cider	6 23	0 4	22 40 "	30
Cider	8 8	0 4	30 "	10
Claret	11	0 4	30–45 "	50
Claret	9 25	0 5	20 "	20
Port wine	19 65	0 9	30 "	10
Port wine	22 6	1 5	30 "	40
White wine	11 5	0 6	30 "	10
Sherry	20 5	1 5	30 "	40
Sherry	19 25	1 5	30 "	30
Dark beer	5 8	2	30 "	10
Red star lager beer	3 75	2	20 "	10
Schlitz beer	5 35	2	20 "	10
Budweiser lager beer	4 9	2	20 "	10
Ballentine's ale	6 3	2	20–35 "	40
Ballentine's ale	6 3	2	20–35 "	40
Bass's pale ale	9 25	1	30 "	10
Bass's pale ale	8 5	1 5	15 "	10
Rye whiskey	46 4	10	10 "	20
Blend whiskey	44 5	10	60 "	20
Holland gin	49	10	35 "	20
Holland gin	52	10	35 "	20
French brandy	50 8	10	20 "	30
Cooking brandy	53 2	10	25 "	30
Absolute alcohol	99 5	10	45–60 "	50

Liquors which contain a high percentage of alcohol may be more toxic or may be less toxic than liquors containing a low percentage of alcohol Sherry and port wine which contain about twenty parts of alcohol are much more toxic than Schlitz's beer and Ballentine's ale,

both of which contain less than seven parts of alcohol. On the other hand, Holland gin, which contains approximately fifty parts of alcohol is much less toxic than any of the beers or wines which range in their contents from three to twenty-three parts of alcohol. Thus it seems that the total poisonous effects of alcoholic beverages are not entirely caused by alcohol but are due in part to other substances.

TABLE II

Showing the Highest Percentage of Alcohol in the Beverages at which Apparently Normal Young were Produced

Beverages	Per Cent Alcohol by Volume in Original Sample	Highest Per Cent Alcohol in Diluted Portion of Sample in which Young were Produced	No. of Females Producing Young
Cider	7.5	.065	10
Cider	6.23	0.1	30
Cider	8.8	0.1	5
Claret	11	0.3	26
Claret	9.25	0.3	6
Port wine	19.65	0.3	10
Port wine	22.6	0.2	15
White wine	11.5	0.1	10
Sherry	20.5	0.9	14
Sherry	19.25	0.9	10
Dark beer	5.8	1	5
Red star lager beer	3.75	0.6	6
Budweiser lager beer	4.9	0.3	20
Schlitz beer	5.35	1	10
Bass's pale ale	9.25	0.05	10
Bass's pale ale	8.5	0.06	10
Ballentine's ale	6.3	1	15
Ballentine's ale	6.3	1	15
Rye whiskey	46.4	2	10
Blend whiskey	44.5	2	10
Holland gin	49	2	20
Holland gin	52	2	20
French brandy	50.8	2	20
Cooking brandy	53.2	2	30
Absolute alcohol	99.5	3–4	50

In further support of this statement a few additional experiments of a somewhat different nature were made. A certain quantity of both claret and sherry were placed upon a steam radiator and allowed to evaporate. In both cases a residue remained. As soon as this residue was thoroughly dried distilled water was added until the original volume was restored. Then each solution was diluted in the same manner as the liquors which contained alcohol. Rotifers were placed in various dilutions of these solutions and the results compared with those obtained from the liquors containing alcohol.

TABLE III

Showing the Comparative Acute Toxicity of Claret and Sherry with and without Alcohol

Beverage	Alcohol in Diluted Portion of Beverage Used	Duration of Life of Rotifers	Alcoholless Liquor Diluted in same Proportion as the Alcoholic Liquor	Duration of Life of Rotifers	No. of Individuals used in each Experiment
Claret	1%	8–10 min	1%	30 min	40
Sherry	2%	15 min	2%	60 min	40

TABLE IV

Showing the Comparative Toxicity of Claret and Sherry with and without Alcohol in Dilutions of which Young Rotifers were Produced

Beverages	Highest Per Cent Alcohol in Diluted Liquor in which Young were Produced	Highest Per Cent Alcoholless Liquor in which Young were Produced Diluted in same Manner as the Alcoholic Liquor	No. of Individual used in each Experiment
Claret	0.3	0.7	25
Sherry	0.9	1.5	25

The acute toxicity of claret and sherry which have the alcohol removed is much less than in the cases where the alcohol is present. Even with the alcohol removed claret is much more toxic than the alcoholless sherry and each of them is more toxic than absolute alcohol. The same fact is shown in the experiments where young rotifers were produced as is indicated in Table IV.

If alcohol is the only toxic ingredient of claret and sherry neither of them ought to produce poisonous effects upon rotifers after the alcohol is removed. These experiments, however, show that these two liquors are very toxic even when they contain no alcohol.

Tables I. and II. show that the wines are strikingly more toxic than the same percentage of absolute alcohol. Chittenden[1] found that wines had a greater inhibitory action on salivary and pancreatic digestion than did a cor-

responding percentage of absolute alcohol This he states is due to their acid properties

Malt beverages, as ales and beers, he states, also have a retarding influence on salivary and pancreatic digestion due to their acidity but it is less marked than it is in the wines Both of the above tables show that some of the ales and beers are decidedly less toxic than the wines Some of them, however, were as poisonous as the wines in the experiments where young were produced, but in the 10–30 minutes experiment on acute toxicity only Bass's ale equaled the toxicity of any of the wines Its toxicity was the highest of all the malt beverages but it did not exceed the lowest toxicity of the wines

The distilled beverages, whiskey, gin and brandy, were conspicuously less poisonous in both sets of experiments than either the wines or malt beverages This is probably due to the fact that in the distilling process of their manufacture the volatile substances are separated from the non-volatile and perhaps toxic materials and are subsequently used in the making of the liquors These distilled liquors approached the point of toxicity of absolute alcohol which was the least poisonous of all the alcoholic solutions used Because of its purity it served as a control with which all the other beverages can be compared

In a comparison it is readily seen that the wines are the most toxic, the malt liquors stand second in point of toxicity, and lastly the distilled liquors are the least toxic of all the beverages and approach nearest to the toxicity of absolute alcohol.

The value of these experiments is to show again that in the three main kinds of alcoholic beverages there are other important toxic ingredients than ethyl alcohol and also to demonstrate that the various alcoholic liquors when reduced to the same percentage of alcohol differ widely in their point of toxicity

The results perhaps explain why different alcoholic beverages have such different effects upon the drunkard even though an equal intoxication is produced. It is generally recognized that brandy produces a certain type of drunkenness and that cider produces another type differing widely from the brandy type. Many of the other liquors also produce a particular type of drunkenness the characteristics of which are typical for each liquor These types of drunkenness are doubtless partly caused, at least, by the non-alcoholic ingredients in the liquors

BIOLOGICAL SOCIETY OF THE PACIFIC COAST

The first meeting of a new society for Pacific coast biologists was held on April 1 at Berkeley, California An afternoon meeting, at which papers were presented by President Jordan and Professor Zinsser, of Stanford University, and Professors Kofoid and Maxwell, of the University of California, was followed by a dinner at the Hotel Shattuck, and by participation, in the evening, in a joint general public meeting of the newly organized Pacific Coast Association of Scientific Societies At this meeting addresses were made by Presidents Wheeler and Jordan, of California and Stanford universities, Professor Kellogg, of Stanford University, and Mr George Dickie, marine engineer, of San Francisco

The Biological Society of the Pacific Coast begins with an active membership of seventy, representing California, Washington, Oregon, Arizona and Utah Three meetings will be held each college year, of which one will be known as the annual meeting and will be held in conjunction with the meetings of the various other societies composing the Pacific Coast Association of Scientific Societies The officers of the society for 1911–12 are Professor Vernon L Kellogg, president, Professor H B Torrey, secretary-treasurer, and Professor H J Maxwell, third member of the executive committee

SOCIETIES AND ACADEMIES

THE HELMINTHOLOGICAL SOCIETY OF WASHINGTON

The fourth regular meeting of the society was held at Dr Stiles's residence on February 9, 1911, Dr. Stiles acting as host and Dr. Pfender as chairman

Mr Foster presented a note on a nematode from the stomach of the pig. This form had been provisionally identified as *Spiroptera strongylina*,

but the location of the vulva in the anterior portion of the body indicates that it is a new species or else that the available descriptions of the European *S strongylina* are in error in describing the vulva as near the anus *Spiroptera strongylina* has been reported from Texas in 1892 by Francis, who states that this species is common there but that the identification is doubtful, and from Kansas in 1910 by Kaupp, who figures the vulva as posterior He may have so figured it as the result of an error of interpretation Specimens in the helminthological collection of the Bureau of Animal Industry were collected by Kilborne as early as 1884 These specimens show the vulva in the anterior portion of the body The European species is usually described as having a smooth mouth, though von Linstow notes six round papillæ The American species has two lips and six long papillæ There are other differences in the ratio of the length of the large and small spicules

The worm occurs half buried in the mucosa of the stomach and is therefore a dangerous parasite Von Ratz in 1897 reported an epizootic due to *Spiroptera strongylina*, in which a number of pigs were seriously affected and some killed The parasite caused sloughing of the gastric mucosa and it is probable that the American species does the same It is therefore of some economic importance

Associated with the American *Spiroptera* were specimens of *Physocephalus sexalatus*, recorded here for the first time from the United States This is also the first record of its occurrence in the domestic pig Former records are from the peccary and the wild boar

Dr Goldberger presented a note on some trematodes of fish The œsophagus presents a notable peculiarity It is ordinarily described as ending at the fork where the intestinal ceca begin In some forms there is said to be no œsophagus present This statement is due to a failure to take into account a structure that is a part of the ceca though it really belongs to the œsophagus This structure is limited posteriorly by a constriction or sphincter, and is really a forked œsophagus, extending from the pharynx to this constriction This structure he has noted in the genus *Arygia* and in *Leuceruthrus*

Dr Goldberger also presented a note on a trematode from a black snake In this trematode (*Styphlodora bascaniensis*) Laurer's canal does not go to the dorsum and open to the exterior, but ends in a globular swelling containing cells like vitelline cells and some other structures interpreted as spermatozoa The worm has a well developed sperm receptacle *Aspidogaster conchicola* has been described as having a similar form of Laurer's canal

In discussing Dr Goldberger's paper, Dr Stiles called attention to the fact that in 1894 he had stated in a paper on *Fasciola magna* that the egg shell was probably formed by the vitellogene glands rather than by the so called shell glands A paper by Goldschmidt in 1909 has given in detail the formation of the egg shell, his conclusions being somewhat similar to those of Stiles in 1894 Dr Ransom stated that he had come to the same conclusion regarding the shell gland of certain bird tapeworms He had thought that possibly the walls of the uterus were partly responsible for shell formation as shells were found only after the eggs had been in the uterus for some time

Mr Hall presented a paper entitled "The Need and Desirability of a Biological Survey of the Parasite Fauna of the United States" The amount of data relative to the occurrence, distribution, habits and importance of the animal parasites of the United States is very small There are few persons who collect material or contribute notes in this field of investigation The large amount of material in the government laboratories at Washington has been largely collected at Washington and at the slaughter houses at big packing centers, and in these cases there is often little data as to the localities where infections were acquired

As a preliminary to a biological survey of our parasite fauna, statements as to the occurrence and distribution of our more important parasites, so far as the occurrence and distribution is known, should be made Such a statement would furnish incentive for additional records, as it is easier to refer to such a record and add to it than to look through our present scattered records, many of which are not available to most persons Conversely, such a record would serve as a guide in looking for parasites As an illustration of the utility of such a survey, it may be noted that the preliminary work on the hookworm made it possible for physicians to add intelligently to the records, thus mapping out the infected areas Conversely, it led physicians to look for the hookworm in those states from which it was recorded or where the records indicated that it would be found, for such records indicate possibilities and probabilities in addition to showing known facts

Such records indicate foci of infection and awaken the interest of persons resident at such foci. They are essential in campaigns of eradication. A study of the distribution, habits and importance of some of our animal parasites may throw light on life histories by indicating a corresponding distribution of intermediate hosts or of other conditions requisite for the life cycle. This would permit of outlining more adequate means of prophylaxis, would make possible more intelligent estimates of the economic importance of our parasites, and would aid in guarding against indigenous and imported species. With such preliminary compilations of records as a nucleus, it should be possible in time to proceed to a real biological survey of our parasite fauna.

Dr. Ransom presented a note on the viability of nematode eggs and larvæ. In some species there is a great difference between the viability of eggs or newly hatched embryos and that of the full grown larvæ. The first two are quickly killed by low temperatures or drying, but the ensheathed larvæ can be frozen for some time, or frozen and thawed alternately without damage. Of two cultures of ensheathed larvæ, one of which was kept out of doors during the winter and the other indoors, the former was found in the better condition at the end of the winter. The probable explanation is that low temperature inhibits activity and in this way conserves the food supply stored up in the intestinal cells of the larvæ. The ensheathed larvæ can also be dried for some time and then revived by the addition of moisture.

Nematodirus filicollis develops to the ensheathed stage before hatching, a period of about a month being required for the development at a temperature of about 70° Fahrenheit, whereas under similar conditions the stomach worm (*Hæmonchus contortus*) hatches in about two days, and does not develop to the ensheathed stage until after hatching. The eggs of *Nematodirus* are much more resistant to low temperatures than those of the stomach worm. A temperature of 12° Fahrenheit was found to kill eggs of the stomach worm in seven to ten days, while eggs of *Nematodirus* were viable at the end of eight weeks after exposure to the same temperature. At 32° to 40°, eggs of the stomach worm were still alive at the end of eight weeks, but were dead after thirteen weeks. The eggs and embryos of *Strongyloides* do not resist drying. In this genus the embryos do not ensheath.

Dr. Stiles presented a note on the progress of the hookworm work in this country, and noted the finding by Stiles and Miller, on the basis of microscopic diagnosis, of cases of hookworm disease in Kentucky. He exhibited maps showing all the counties known to be infected.

MAURICE C. HALL,
Secretary

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

THE 453d regular meeting of the society was held in the hall of the Public Library, March 28, 1911, 8:00 P.M., with Mr. George R. Stetson, vice-president of the society, in the chair.

Professor R. B. Dixon, of Harvard University, read a paper on "Polynesian Mythology." After a geographical survey of the islands of the Pacific, including Polynesia, Melanesia, Micronesia and Malasia, the speaker gave a delineation of the pantheon and a concise exposition of the theology entertained, with greater or lesser variations, by the different tribes of these islands. The gods are broadly divided into greater and lesser ones. In addition to these there are ancestral and totemic deities. The four great gods are Tane (dialectically, Kane), Tu (Ku), Tangaroa (Tanaloa) and Rongo (Lono, also Oro). The lesser gods are for the most part considered as their offspring. Of the four great gods Tane is the greatest. He is conceived as self-evolved, existing from eternity, the father of men, and is connected with the sky. He is supreme in the Hawaiian Islands and New Zealand, although he had there no temples and scarcely received any worship, while in Samoa and central Polynesia at large he is almost unknown. The same is the case with Rongo, the god of agriculture, and Tu, the god of war. On the other hand, Tangaroa, who forms a group by himself, enjoyed great honor in Samoa and the central portion of Polynesia, but was associated with darkness and evil in Hawaii and seems to be a late comer into Hawaii, imported from Tahiti or the Marquesas Islands. There are, as a rule, no images made of the great gods. The only representations made of them are stone pillars or wooden poles swathed in tappa or mats. The mythology of the other islands of the Pacific Ocean, as that of Melanesia, Micronesia, agrees in some portions with that of Hawaii and New Zealand, in others with that of Samoa and central Polynesia.

The paper was discussed and commented upon by many of those present.

SOME FACTORS IN THE INSTITUTE'S SUCCESS[1]

IT is fifty years to-day since Governor Andrew signed the charter of the Massachusetts Institute of Technology There are many in the community who have watched the growth of this institute ever since The dean of those who have been intimately associated with its government is Mr William Endicott—a tireless worker in its interest He writes to express regret that he can not be with us to-day, on account of a recent family bereavement, and adds "It has been one of the greatest pleasures of my life to watch the Tech's triumphant progress from small beginnings to its present assured position as one of the leading scientific institutions of the world" In spite of (perhaps, because of), its youth, and in spite of (if not because of) its earlier struggles and difficulties, it is now absolutely in the front rank—a recognized leader in its chosen field, held in respect and honor everywhere Why this conspicuous success? It is a question that has often been discussed in the reports of commissioners and other distinguished visitors from abroad, and in the councils of educators at home Many are the explanations offered—the earnestness and devotion of the faculty, the spirit and energy of the students, the loyalty and organization of the alumni, the completeness of its equipment, the number and distinction of its instructors, the variety of its courses, the thoroughness with which the students'

[1] Address by the president of the Massachusetts Institute of Technology at opening of the Congress of Technology, April 10

knowledge and ability is tested, the practical character of the instruction, the close touch with industries, the power of adaptation and resources manifested by its graduates, and so forth. These are doubtless all contributory causes and are the causes that naturally suggest themselves to a student not specially versed in the history of the institute.

At this season, when we are celebrating the fiftieth anniversary of its chartering, it seems natural to lay somewhat more emphasis on historic causes.

The more one looks into the matter, the more is he impressed by the fact that although many enlightened men cooperated in launching the institute on its course, the enthusiasm and the guiding power were supplied by one man—Rogers. His choice of Boston as a suitable place for the new venture was made deliberately. Be it remembered that he was not a New Englander, that he was nearly sixty years of age when the institute was founded, and that until then he had spent the greater part of his active life in the southern states. To the serenity of outlook on human affairs that marks the scientist and the philosopher, he added an element of passion (perhaps derived from his Irish ancestors), when he touched the realm of education. Nowhere in the world is the supreme worth of children more thoroughly appreciated than in America; nowhere is the preparation for their future regarded more generally as one of the holy offices; nowhere in America is this sacred duty more clearly recognized and more anxiously discussed than in Boston. So Rogers placed the institute here, not because of the paucity of schools in this neighborhood, but because of their abundance; not because of their weakness, but because of their strength. This, he thought, should be good ground in which to sow fresh educational seed, and ere long his expectations were fully justified. Men of light and leading in the community gave hearty support to the new venture. Governor Banks favored state aid to the institute on the ground that such an institution would "keep the name of the commonwealth forever green in the memory of her children." His successor, Governor Andrew, who signed the institute's charter, was greatly interested, and did all that he could to help. "We ought," he said, "to start out on a broad gauge and inaugurate a great plan looking to the long future of the commonwealth." An imposing array of individuals and of societies petitioned the legislature to aid in forwarding the new scheme. Had Rogers chosen his location less wisely, he might easily have failed to enlist such support. The advantages of his chosen ground became still more apparent at the critical time when men had to be found to carry out the new ideas. He realized that this was the point where he was to gain victory or suffer defeat, and in spite of the exceptional difficulties presented, he soon succeeded in surrounding himself with the right men. The original faculty of ten professors formed a vigorous group, with great reserve of strength, physical as well as mental. They all lived to a ripe old age, and nearly all earned distinction in their own fields. Four of the men are still happily with us, including the professor of analytical chemistry, Charles W. Eliot, whose vigor is not perceptibly diminished after forty years of exacting toil in the presidency of Harvard.

It seems clear, then, that one important factor in the institute's success has been the place of its birth. And if the place was propitious, the time was in some respects peculiarly so. It was a period of upheaval, to be followed immediately by one of rapid forward movement. The charter was granted within a few days of

the breaking out of hostilities marking the beginning of the great war The national crisis, of course, turned men's thoughts away from science and from education About a fortnight after the granting of the charter, Rogers attended a meeting of the Thursday Evening Club, and was called upon to speak on some matter pertaining to science According to a newspaper report of the time "Professor Rogers very gracefully declined to discuss the topic proposed, but made instead a stirring appeal to the club in favor of providing a regiment of our brave volunteers with knapsacks" Such a time seemed peculiarly unpropitious for initiating a new educational movement, and no doubt the war checked the early growth of the institute very seriously. However, after a few years, the nation was ready to turn with undivided mind to the great problems of development, and the seed having been sown earlier in good ground, the institute sprang up rapidly and reaped the harvest of hope engendered by the settlement of the grave moral and political questions to which the war was due In the quieter field of human activity, the field of thought, the world was experiencing an equally great upheaval. Darwin's great book had just been published, with results of the first magnitude in shaping the lives on which the world of intellect was to move forward for the next half century Kirchhoff's idea of spectrum analysis was just opening a new era in physics and in astronomy Faraday was nearing the end of his great career, but his splendid discoveries had not yet borne fruit in the field of practise His work, however, was having its influence on the mind of Maxwell, the greatest of whose scientific achievements was announced in 1865, the year in which the institute actually began to work. The world was just entering on a period of remarkable activity in the practical applications of science The scientists were still struggling with the difficulties of cabling The Boston of those days was somewhat proud of its critical spirit and in 1859 a writer in the Boston *Courier* proved at great length that all the so-called messages through the Atlantic cables were fictitious, mere shams to save the stock for a time Edison, who was living in Boston in 1868, and whose son is an under-graduate at this institute to-day, was just beginning his wonderful career as an inventor. A few years later, one of the greatest marvels of scientific achievement, the electric transmission of speech, was to be demonstrated in this very city, indeed, in this very hall, by Alexander Graham Bell, through his invention of the telephone

At such a time, and in such a place, an institution devoted to science and its applications had at least an excellent chance of success. The institute would, however, never have achieved what it has, if other forces had not contributed to its success Some of these have been mentioned earlier, but there is one of the very first importance, rarely, I think, appreciated at its real value, to which special reference should be made *There has never been any uncertainty or indefiniteness as to what the institute is aiming at in its scheme of education* Every serious student of education is struck by the fact that so many schools and colleges drift around, apparently without compass or rudder, with no definite idea as to what port they are trying to reach, or how they should go to reach it Here, at any rate, is an institution that, *from the very outset*, has had very definite ideas on these matters, whether those ideas be right or wrong Most of these ideas are set forth in Rogers's "Object and Plan," which forms a charter of the institute not less valuable than that which Governor Andrew signed At the time of writing it, Rogers was no novice in education He

was not far short of sixty, and had taught and thought on educational problems since very early manhood. He had discussed some such project as that of the institute for twenty years at least, and his ideas thereon had gradually clarified and crystallized, as can be seen from the record of their development which is accessible to all.

Rogers has sometimes been charged with setting up a school in a spirit of antagonism to existing institutions. There is no ground for such a charge. He was too catholic in his tastes to fail to appreciate the good in others, and in advocating something new, he took the safe ground that there was room for difference in the field of education. He knew, as every educated man must know, that the fear of what is called *useful* knowledge, is exaggerated, and for the most part groundless. He knew, as others do to-day, that the oldest universities all began with a clear recognition of the bearing of their studies on definite callings, and he recognized clearly that it was not a merit but a defect of these schools that most of them had failed to keep pace with the changes in the character of human occupations that time had brought forth. He saw, as Lowell did, that "new times demand new manners and new men" and that new conditions demand new schools. For the guidance of the new school, he laid down a few simple, but far-reaching, principles, which have governed the institute ever since. The first of these is the *importance of being useful*. There is, of course, no necessary antithesis between the individual and the social end in education. However, the laying of the emphasis *is* important, and Rogers laid it unhesitatingly on efficiency in the service of society. In his first address to the students at this institute, he set forth the *value* and the *dignity* of the *practical* professions for which they were to prepare themselves. (Rogers, himself, be it remembered, was a pure scientist, President of the National Academy of Sciences, the friend of Darwin, Kelvin, Helmholtz, and the like.) In earlier discussions with his brother with reference to the plan of the institute, emphasis had been laid on "the value of science in its great modern applications to the practical arts of life, to human comfort, and health, and to social wealth and power." And so when the institute was actually founded the importance of science was kept steadily in view. He regarded the scientific habit of thought as specially valuable in practical affairs and consequently in education he laid greater stress on broad principles and their derivation than on details of fact, and he held that the *spirit* of science was more to be desired than all the gold of scientific knowledge. These are his words: "In the features of the plan here sketched, it will be apparent that the education that we seek to provide, although eminently practical in its aims, has no affinity with that instruction in mere empirical routine which has sometimes been vaunted as the proper education for those who are to engage in industries. We believe, on the contrary, that the most truly practical education, even in an industrial point of view, is one founded on a thorough knowledge of scientific laws and principles, and one which unites with habits of close observation and exact reasoning, a *large general cultivation*. We believe that the highest grade of scientific culture would not be too high as a preparation for the labors of the manufacturer." It will be seen from this that Rogers made no fetish of science, and that he welcomed every really liberal study. Some of the champions of the new school joined in the attack on the older learning, but Rogers had no sympathy with such views. "The recent discussions here and elsewhere," he said, "on the relative value of scientific and classical cul-

ture seem to threaten an antagonism which has no proper foundation in experience or philosophy" And although the study of the classics has never formed part of the institute's courses, history, economics, languages and literature enter into its curricula far more extensively than is generally supposed

Apart from his appreciation of the value of all sound learning, Rogers saw clearly that the whole controversy as to the relative merits of science and the classics in the field of education missed the mark by placing the emphasis in the wrong place He understood that when one gets to the root of things in education, the *method* rather than the *subject* is of supreme importance, and his insistence on the value of method in teaching was the cardinal doctrine in his creed and the one that has contributed most to the success of the institute Doubtless his knowledge of the history of science turned his thoughts in this direction He must have pondered over the question, as every serious student has done, why throughout the ages the world stood so still in the realm of science It was not for lack of intellectual power, for no one who has examined the matter can fail to recognize that there really were giants of old The failure came through attacking the problems by the wrong method And Rogers concluded that much of the failure in education was due to similar causes What method, then, is the right one? His fundamental idea here was not original with Rogers It has been clearly expressed before, but rarely, if ever, adopted definitely as the basis of educational method and applied systematically throughout The idea is familiar to us all to-day, the idea of *learning by doing* "How can a man learn to know himself?" asked Goethe "Never by thinking, but by doing" Add to this the doctrine of Carlyle that "the end of man is an action and not a thought, though it were the noblest," and you have the whole thing in a nutshell Carlyle is often quoted as having said that the modern university is a great library He would have been truer to his own doctrine if he had said that the modern university is a great laboratory "The institute," General Walker was fond of saying, "is a place not for boys to play but for men to work" Boys and men alike learn most effectively by working for themselves, and the *do-it-yourself* method has been, I believe, the greatest factor in the success of this institute of technology

Whatever be the explanation, there can be no doubt about the fact of its success It is not merely that the institute is now the largest institution of its kind in this country, and as regards the extent and variety of its courses and equipment, the most nearly complete in the world It is not merely that it has grown so that there are a hundred students to-day for every one that took the preliminary course scarcely fifty years ago, and that amongst these students there are men drawn by its reputation from the greatest universities of England, France and Germany, as well as from the leading schools and colleges throughout this union It is not merely that its teaching staff has expanded so that it contains to-day more than two hundred and fifty men, and that amongst its hundred professors are to be found many men of prominence, and not a few of national and indeed international reputation It is not merely that amongst its graduates, there are men of the front rank as pioneers of knowledge in the field of pure science, nor that its ten thousand alumni have played so great a part in the development of the nation's industry and commerce, and in the preservation of the public health The most striking fact, when one

considers the institute's youth, is the fact emphasized on an earlier anniversary by Mr Augustus Lowell and expressed by him in the phrase, "The M I T is *pre-eminently a leader in education*" Its educational ideals and methods have been studied and almost everywhere the trend to-day is in the direction in which the institute has long been moving

To celebrate the fiftieth anniversary of the granting of the institute's charter a congress of technology has been arranged At this congress, which opens to-day, and will be in full activity to-morrow, prominent alumni and members of the faculty are to deal with problems raised in the field of their own specialty The guiding idea throughout is the gain in efficiency that comes from the application of scientific methods to the treatment of the great practical problems of the day The business world must be weary of amateur suggestions for the conduct of its affairs and there is danger of damage to a great cause by too much talk The problem of increased efficiency is no new problem to the man of affairs, and there is much that is thrust upon him in these days that he must have known for years On the other hand, a sane and serious discussion by men who know their subject and speak from experience must always be welcome, and doubtless in the proceedings of this congress there will be much of interest to the business men who are alive to the necessity of advancement and who are on the alert for suggestions that may be helpful in their own affairs

A glance at the program will give some idea of the variety of the interests represented, but more thorough study is needed to realize in any adequate measure that the work of this institute touches practical life at a thousand points What the institute has achieved in half a century has fully justified Rogers's statements when making his first appeal for public support "I am sure," he said, "that I speak from no impulse of mere enthusiasm when I say that this new undertaking presents an opportunity of practical beneficence in connection with education which is not only peculiar, but without precedent in this country My experience as a teacher and my reflections on the needs and means of industrial instruction assure me that this enterprise, when fully understood, must command the liberal sympathy of those who aim to make their generosity fruitful in substantial and enduring public good"

R C MACLAURIN

HENRY PICKERING BOWDITCH

DR BOWDITCH was one of the foremost leaders in the scientific development of America In the establishment of university laboratories for research he was a pioneer and for forty years he exerted a wide and profound influence upon the progress of physiology, of medical science and of university education It was the man himself which counted, for upon every one his sincerity, his absolute single-mindedness, his intellectual power and his genial spirit made a lasting impression, and created confidence in himself

Bowditch was born April 4, 1840, at Boston He descended from the best New England stock. Nathaniel Bowditch, the mathematician, well known to all navigators, was his grandfather His father was a successful business man, who bought a large estate at Jamaica Plain, upon a beautiful hill, which has a commanding view both of Boston and of the country for many miles around This hill is intimately associated with Dr Bowditch in the thought of all who knew him, for he continued as one of a large family colony to dwell on it until his death

He entered Harvard College, graduated in 1861, and entered the Lawrence Scientific School, but in November of that year he volunteered and became a second lieutenant in

the First Massachusetts Cavalry His regiment went south in January, 1862, and from that time until the close of the civil war he was almost continually in active service He resigned June 3, 1865, being then major of the Fifth Massachusetts Cavalry He reentered the scientific school, and passed from there to the Harvard Medical School, from which he received the degree of M D in 1868 He frequently referred with gratitude to the influence of Jeffries Wyman upon his own scientific development

With the approval and encouragement of his father he decided to devote himself to a scientific career, and as it was impossible to obtain satisfactory training in medical science at that time in this country, he went to Europe to study in Paris, Bonn and Leipzig At the latter place he worked under Carl Ludwig, of whom he always spoke with reverence and affection The great master found an apt pupil in the young American, and the pupil rapidly became a master himself Bowditch had remarkable mechanical talents Ludwig was wont to tell how Bowditch arrived in the laboratory when the kymographion invented by Ludwig was beginning to be used, and the automatic record showed only the movement of the muscle or heart, the time of stimulation being marked by hand Bowditch immediately set to work and produced the devices for recording the actual time and the duration of the stimulus automatically Many valuable ideas are simple, like Bowditch's invention, and after they have been produced appear obvious and invaluable, but in reality lucid simplicity is one of the essential characteristics of a superior intellect Bowditch was endowed with this quality in a high degree, and it showed itself throughout his life in the perfection with which he worked out the problems he had to deal with In Ludwig's laboratory he carried through his researches on the heart, which were of fundamental importance and therefore rank among the cherished classics of physiology

He remained abroad until 1871, returning to Boston in September of that year to become assistant professor of physiology at the Harvard Medical School Up to 1871 Dr Oliver Wendell Holmes had lectured on anatomy and physiology, thereafter the professorship was divided Holmes restricted himself to anatomy Physiology was assigned to Bowditch In 1876 he was made full professor In 1906 he resigned his position owing to failing health, and was made professor emeritus He met the increasing limitations of his illness with perfect courage Courage was one factor of his power over others Death came quietly on March thirteenth last

The Harvard Physiological Laboratory was the first modern laboratory for instruction and research in the medical sciences to be founded in America It was wonderfully equipped for the period of its foundation, for Bowditch put into the laboratory the large supply of apparatus, his personal property, which he had brought back from Europe He at once began a course of lectures in physiology, which excelled so enormously anything which had ever been presented in America, that the effect was instantaneous The consequences were revolutionary, for his work at Harvard initiated the creation of the new medical standards The present writer was his first research pupil and recalls vividly the revelation opened by admission to the new laboratory

During thirty-five years Bowditch was an efficient leader in the development of the Harvard Medical School, in the advancement of physiology and other medical sciences in the United States, and he found time besides to promote energetically many causes of civic betterment Very few men have contributed so much as he to the elevation of medical education He stood for the highest ideals of progress and maintained always that the old-fashioned "practical" physicians must be replaced by men scientifically trained and animated by the scientific spirit For this principle he carried on a long campaign In the face of opposition and much early discouragement he kept steadily at this great task, and had the satisfaction in the end of seeing his cause triumphant The superiority of the laboratories abroad, especially in Germany a generation since, made a profound impression

on American students. Bowditch was one of a group of young physicians who strove successfully to found at Harvard laboratories modelled on those of Germany. The result of their efforts was the medical school building on Boylston Street, which, when it was dedicated in 1883 was easily the best for its purposes in America. From the time of the opening of this building until 1893 Bowditch acted as dean of the medical school, and during this period the school improved with unparalleled rapidity largely owing to his personal influence. He was a man who had visions of better conditions, and worked to make them realities. It was his vision which first conceived a second new medical school on a magnificent scale of equipment, and it was mainly by his persuasion that the Harvard authorities agreed to attempt to carry out the plan. He threw himself with characteristic ardor into the work. Together with Dr. John Collins Warren and others he labored, and the magnificent laboratories, opened in 1906, which the school now possesses, commemorate his devotion and success. With the completion of the cluster of five hospitals at present under actual construction or soon to be begun, which will surround the laboratories, Bowditch's dream will be fulfilled. Fortunately he lived to know that this fulfilment was assured, though he could not see it completed.

Outside causes, sometimes professional, sometimes civic, often appealed to him. Thus he was one of the principal founders of the American Physiological Society, to the affairs of which, as of the National Academy and other scientific associations, including the International Physiological Triennial Congresses, he gave of his time generously and always helpfully. With a small group of colleagues in Boston he took up psychical research, and aided in founding and for several years in managing the American society. His open-mindedness was shown in this matter and was characteristic, but his experience finally rendered him extremely skeptical as to the reality of telepathy and other alleged psychical phenomena. He was a trustee of the Elizabeth Thompson Science Fund from its foundation in 1886 until 1906. Much of the credit of the success of that fund belongs to him. In Boston he served several years on the school committee, and also as a trustee of the Public Library. Whatever he undertook he tried to do well and with such complete singleness of purpose that every one with whom he was thrown in contact instinctively trusted him.

The manifold activities, which have been referred to, encroached upon his time, and in later years he occasionally asked a friend whether his life would not have been of greater service, if he had devoted himself exclusively to experimental physiology. His success in more extended research would have been great, for in all his actual researches he was eminently successful. Thus, his work on the growth of children remains still the best on the subject. His investigations on the indefatigability of nerves, on the knee-jerk, on ciliary motion and other subjects are important and are also models both of thoroughness of experimentation and of clearness of presentation. Nevertheless, one must reply to Bowditch's own question that his life was well and wisely spent, as measured by the value of his services to the general welfare. In view of his great efficiency in promoting not only physiology but science in general and in elevating medical teaching, we must admire with grateful appreciation his career, which has been a powerful factor in the advance of research and education in America.

His own researches only partially indicate his range and efficiency as an investigator, to measure which fully one must know the work of William James, Stanley Hall, Southard, Lombard, Porter, Cannon and many others, who worked in his laboratory.

He received many tokens, both personal and official, of the high esteem in which he was held. He was an honorary member of numerous scientific bodies, and received honorary degrees from Edinburgh, Cambridge (England), Toronto, the University of Pennsylvania and his own Harvard.

Dr. Bowditch married Miss Knauth in 1871. She was the daughter of a Leipzig banker,

whose house was the center of delightful hospitality to many Americans, studying at Leipzig. He found great happiness in his home life, in his children and grandchildren, and also in the numerous friends, whom he attached not only by his unusual abilities but by his personal charm. He was social by nature, keenly humorous, warm and faithful in his attachments, full of the zest of life. He was profoundly modest and seemed never to know how high his abilites were estimated by others. He never quarrelled, but was for every good cause he championed a good fighter. Perhaps his most distinguishing trait was his remarkable combination of keen practical sense in the use of means with enthusiasm in the pursuit of ideal aims. With all his buoyant vitality, with all his eager interest in men and affairs, he was essentially an idealist, who won the love and admiration of many friends both in Europe and America.

C. S. Minot

SAMUEL FRANKLIN EMMONS

The death of Samuel Franklin Emmons at his home in Washington, D. C., on March 28, 1911, after an illness lasting only five days, removed from the ranks of American economic geologists the one who, by virtue of his influence on the progress of his branch of science and by his long and illustrious service, worthily stood at their head. For the last few years Mr. Emmons's increasing infirmity had given concern to his friends, but his own cheerfulness and serenity were unaffected by bodily weakness and when his colleagues missed him from his desk at the Geological Survey offices during the few days before his death they believed merely that a cold in conjunction with unseasonable weather confined him to his house. None foreboded the fatal ending of his illness.

Born on March 29, 1841, in Boston, Mass., the home of his ancestors since 1640, Mr. Emmons at his death lacked one day of his seventieth year. His great-grandfather, Samuel Franklin, after whom he was named, was a first cousin and close friend of Benjamin Franklin.

Mr. Emmons graduated from Harvard College in 1861 and went abroad to continue his studies, first at the Ecole Impériale des Mines in Paris and afterwards at the Bergakademie in Freiberg, Saxony. He returned to the United States in 1866 and after spending eight months in visiting the mining districts of the west he joined Clarence King as a volunteer assistant in the United States Geological Exploration of the fortieth parallel, receiving his official appointment in the winter of 1867-8. For nearly ten years he remained with this organization, seeing varied service, gaining that wide knowledge of the geology of the west that he afterwards turned to such good use, and contributing to the published results of the exploration. With Mr. Arnold Hague he was joint author of the second volume of the great fortieth parallel series, entitled "Descriptive Geology," and he had a part also in the preparation of Volume III., "Mining Industry." His work carried him to Virginia City in the winter of 1867–8, to Mono Lake in March, 1868, to the unknown mountain ranges of central and eastern Nevada and of western Utah in the following summer, to the Wasatch Range and to the region adjacent to Great Salt Lake in 1869, to Mount Rainier in 1870, and to the Uinta Mountains in 1871 and 1872.

Having accomplished his duties in connection with the fortieth parallel survey, Mr. Emmons, in the autumn of 1877, returned to the west and engaged in the then stirring business of raising cattle, near Cheyenne, Wyoming. When, however, Clarence King in 1879 organized the United States Geological Survey and became its first director, he sought out his friend and associate of earlier years and placed Mr. Emmons in charge of the economic geology of the Rocky Mountain division with instructions to make a detailed survey of the newly opened Leadville district. During the field-work at Leadville, which lasted until 1881, Mr. Emmons collected the statistics of the precious metals in the Rocky Mountains for the Tenth Census and in Volume XIII. ("Precious Metals") of that publication, jointly with Dr. George F. Becker,

introduced the plan of presenting outlines of the geological relations of the ore bodies in connection with the statistical data

The monograph and atlas on the "Geology and Mining Industry of Leadville" were published in 1888, although an abstract of results had appeared as early as 1882 This great work established the reputation of its author, not only with men of science, who recognized the care and thoroughness of the basal observations, the essential soundness of the deductions and generalizations the breadth of view displayed, and the masterly treatment and presentation of the material, but also with the miners, who found that they could sink shafts with the certainty of finding contacts and faults substantially as Emmons had drawn them in his remarkably accurate sections The passing years, while they have necessitated some modifications of the theoretical conclusions advanced in this monograph, have brought out more and more clearly the sound basis of honest ability and conscientious workmanship upon which lasting fame must rest The Leadville report was preceded in publication by Becker's monograph on the "Geology of the Comstock Lode and Washoe District" and by Curtis's less extensive report on the "Silver-lead Deposits of Eureka, Nevada," but with these, and probably more decisively than these, it marked the beginning of a new era in economic geology and became the model for the numerous monographic reports on western mining districts that have since been published by the United States Geological Survey

Up to a few years ago Mr Emmons continued in general charge of the investigations on western ore deposits carried on by the U S Geological Survey and many studies were planned and completed under his supervision and with his suggestive advice In some reports he appeared as collaborator—notably in those on the "Economic Geology of the Mercur Mining District" (U S Geol Survey Ann Rept, 1895), "Economic Resources of the Northern Black Hills" (Professional Paper No 26), and the "Economic Geology of the Bingham Mining District, Utah" (Professional Paper No 38), in others his share was less patent, although perhaps scarcely less important In the series of folios of the Geologic Atlas of the United States he wrote part of No 9, "Anthracite-crested Butte, Colo," parts of No 38, "Butte Special, Mont" and No 65, "Tintic Special, Utah," and the whole of No 48, "Ten-mile Special, Colo" During this period of administrative and directive work he collaborated also as senior author in the monograph (No 27) on the "Geology of the Denver Basin, Colo" (1896) and published a paper on the "Mines of Custer County, Colo" (1896)

Among the many important contributions made by Mr Emmons to scientific journals and to the proceedings of societies may be mentioned "The Genesis of Certain Ore Deposits" (1887), "Notes on the Geology of Butte" (1887), "Structural Relations of Ore Deposits" (1888), "On the Origin of Fissure Veins" (1888), "Orographic Movements in the Rocky Mountains" (1890), "Geological Distribution of the Useful Metals in the United States" (1894), "The Secondary Enrichment of Ore Deposits" (1901), "Theories of Ore Deposition Historically Considered" (presidential address, Geological Society of America, 1904), "Los Pilares Mine, Nacozari, Mexico" (1906), and "Biographical Memoir of Clarence King" (read before the National Academy of Sciences in 1903, published in 1907)

The paper on the secondary enrichment of ores was the outcome of observations and study extending over many years and it is characteristic of Mr Emmons's largeness of mind that he discussed this principle freely with his assistants and showed no haste to secure to himself priority in announcing results whose great scientific and practical importance he fully realized

At the fifth session of the International Geological Congress, held in Washington in 1891, Mr. Emmons served as general secretary and was the author of a large part of the geological guide prepared for the excursion by members of this congress to the Rocky Mountains. He was also vice-president at

the sessions of the congress held in 1897 and 1903

Mr Emmons became a fellow of the Geological Society of London in 1874 and joined in 1877 the American Institute of Mining Engineers, of which organization he was thrice vice-president While engaged in his early work in Colorado, with headquarters at Denver, he helped in 1882 to organize the Colorado Scientific Society, was elected its first president, and contributed extensively to its proceedings He also took part in the founding of the Geological Society of America, of which he was chosen president in 1903 In 1892 he was made a member of the National Academy of Sciences and he filled the office of treasurer of that body from 1902 to the time of his death He was a charter member of the Mining and Metallurgical Society of America and held active or honorary membership in many other scientific societies in this country and abroad In 1909 both Harvard and Columbia universities conferred upon him the honorary degree of Sc D

During the later years of his life Mr Emmons, freed from the cares of official administration, returned to his studies at Leadville and, in association with Professor John D Irving, of Yale University, was engaged in extending his earlier results in the light of the additional facts brought out by extensive mining operations continued through two decades Although some of this newer material was published in 1907 as Geological Survey Bulletin No 320 on "The Downtown District of Leadville, Colo," Mr Emmons did not live to see the publication of his final results which will, however, before long be issued by the Geological Survey

He was one of the founders, in 1905, of the journal *Economic Geology* and continued his able and enthusiastic cooperation in its behalf up to the time of his death

Tall in person, with a figure suggestive of activity and endurance rather than of robust strength, naturally dignified in bearing and distinctive of face, Mr Emmons, notwithstanding his genuine modesty, was a man to attract notice in any assembly One element of his forceful character was a peculiar shyness recognizable by his friends in a certain constraint of manner and bluntness of speech likely to be misunderstood by those who were unaware of his real kindness of heart and of his genial outlook on life A steadfast and devoted friend, he appeared to be incapable of cherishing resentment and his mind rose high above those petty considerations of priority and credit that too often vex and humiliate the souls of scientific men in spite of their better natures

The chief characteristics of his work were thorough painstaking honesty of method, wide and penetrating vision in the interpretation of his facts, remarkable soundness and stability of judgment, and clarity of exposition Himself able to express his thought in unusually clear and felicitous language, Mr Emmons was an invaluable critic, not only of substance but of form, and those geologists who in their younger days were so fortunate as to receive his kindly yet keen criticism, have found their appreciation of what he did for them grow more and more with the passing years and will ever hold him in grateful remembrance His own writings are an eloquent protest against the view that sound science can find appropriate expression in slovenly writing

Mr Emmons was three times married—in 1876 to Weltha Anita Steeves, of New York, in 1889 to Sophie Dallas Markoe, of Washington, and in 1903 to Suzanne Earle Ogden-Jones, of Dinard, France, who survives him He left no children

In the course of his long life Mr Emmons had seen the far west that he knew and loved so well make astonishing progress, especially in the mining industry, and he had the satisfaction of knowing that by his work he had materially advanced this development He had received unsought and bore modestly the honors that men of science most prize His name not only stood high on the rolls of science, but was known to miners throughout the Rocky Mountain region as that of the man who more than any one else had applied geological knowledge in a way to convince them

of its value Increasing physical disability neither embittered his cheerful spirit nor diminished his interest in science or in the general affairs of life When he withdrew from activities in which he would once have joined it was with the unobtrusive thoughtfulness for others that foresaw some possible hindrance that his presence might occasion His scientific associates have lost his genial sympathy, his ever ready help in worthy effort, and his ripe judgment in decisions of moment, but the inspiration of his life and character remain and probably each of those who loved him has had the heartfelt wish that when his own turn came death might summon him with like gentleness, after a life of usefulness and honor

F L Ransome

THE CONGRESS OF TECHNOLOGY

The fiftieth anniversary of the Massachusetts Institute of Technology was celebrated on April 10, 1911 On the afternoon of April 10 President Maclaurin read the address given above It was followed by an address by Professor W H Walker on the spirit of alchemy in modern industry, and by one on technology and the public health by Professor C-E A Winslow On Tuesday an elaborate program of special papers was given as follows

SECTION A—SCIENTIFIC INVESTIGATION AND CONTROL OF INDUSTRIAL PROCESSES

Chairman, Professor W H Walker

"The Conservation of our Metal Resources," Albert E Green, '07, electro metallurgical engineer, American Electric Smelting and Engineering Co, Chicago

"Some Causes of Failures in Metals," Henry Fay, professor of analytical chemistry, Massachusetts Institute of Technology, Boston

"Metallography and its Industrial Importance," Albert Sauveur, '89, professor of metallurgy, Harvard University, Cambridge, Mass

"Thirty Years' Work in Boiler Testing," George H Barrus, '74, expert and consulting steam engineer, Boston

"Coal Combustion Recorders," A H Gill, '84, professor of technical analysis, Massachusetts Institute of Technology, Boston

"An Electric Furnace for Zinc Smelting," Francis A J FitzGerald, '95, consulting chemical engineer, Niagara Falls, N Y

"Improvements in Cotton Bleaching," Walter S Williams, '95, textile expert, Arthur D Little, Inc, Boston

"The Work of Engineers in the Gas Industry," Frederick P Royce, '90, vice president, Stone & Webster Management Association, Boston

"The Chemist in the Service of the Railroad," H E Smith, '87, chemist and engineer of tests, The Lake Shore & Michigan Southern Railway Co, Collinwood, Ohio

"The Control of Thermal Operations and the Bureau of Standards," George K Burgess, '96, associate physicist, Bureau of Standards, Washington, D C

"The Debt of the Manufacturer to the Chemist," Hervey J Skinner, '99, vice president, Arthur D Little, Inc, Boston

"Prevention and Control of Fires through Scientific Methods," Edward V French, '89, vice president and engineer, Arkwright Mutual Fire Insurance Co, Boston

"Research as a Financial Asset," Willis R Whitney, '90, director, Research Laboratory, General Electric Co, Schenectady, N Y

"The Utilization of the Wastes of a Blast Furnace," Edward M Hagar, '93, president, Universal Portland Cement Co, Chicago

"Development in Paint and Varnish Manufacture," E C Holton, '88, general chemist, The Sherwin Williams Co, Cleveland, Ohio

"Reclamation of the Arid West," Frederick H Newell, '85, director, U S Reclamation Service, Washington, D C

"Some Problems of High Masonry Dams," John R Freeman, '76, consulting engineer, Providence, R I

"Some New Chemical Products of Commercial Importance," Salmon W Wilder, '91, president, Merrimac Chemical Co, Boston

SECTION B—TECHNOLOGICAL EDUCATION IN ITS RELATIONS TO INDUSTRIAL DEVELOPMENT

Chairman, Dr Arthur A Noyes

"The Elevation of Applied Science to an Equal Rank with the So called Learned Professions," Mrs Ellen H Richards, '73, instructor in sanitary chemistry, Massachusetts Institute of Technology, Boston

"The Engineering School Graduate, His Strength and His Weakness," H P Talbot, '85,

professor of inorganic and analytical chemistry, Massachusetts Institute of Technology, Boston

"Development of Mining Schools," Robert H Richards, '68, professor of mining engineering and metallurgy, Massachusetts Institute of Technology, Boston

"The New Profession of Economic Engineering," Roger W Babson, '98, president, Babson's Statistical Organization, Wellesley Hills, Mass

"Instruction in Finance, Accounting and Business Administration in Schools of Technology," Harvey S Chase, '83, certified public accountant, Boston

"Technical Education and the Contracting Engineer," Sumner B Ely, '92, vice president, Chester B Albree Iron Works Co, Allegheny, Pa

"The General Educational Value of the Study of Applied Science," Alan A Claflin, '94, president, Avery Chemical Co, Boston

"The Influence of the Institute upon the Development of Modern Education," James P Munroe, '82, president, National Society for the Promotion of Industrial Education, Boston

"The Training of Industrial Foremen," Charles F Park, '92, associate professor of mechanical engineering, Massachusetts Institute of Technology, director of Lowell Institute School for Industrial Foremen, Boston

"The Responsibility of Manufacturers for the Training of Skilled Mechanics and Shop foremen," Arthur L Williston, '89, principal, Wentworth Institute, Boston

"The Function of Technical School Laboratories," H W Hayward, '96, assistant professor of applied mechanics, Massachusetts Institute of Technology, Boston

"Technical Education—Its Function in Training for the Textile Industry," Charles H Eames, '97, principal, Lowell Textile School, Lowell, Mass

"The Contribution of the Institute of Technology toward Negro Scientific Thought," Robert R Taylor, '92, director of industrial training, Tuskegee Institute, Tuskegee, Ala

SECTION C—ADMINISTRATION AND MANAGEMENT

Chairman, Dr Davis R Dewey

"An Object Lesson in Efficiency," Wilfred Lewis, '75, president, The Tabor Mfg Co, Philadelphia, Pa

"The Scientific Thought as applied to Railroad Problems," Benjamin S Hinckley, '99, engineer of tests, N Y, N H & H R R Co, Boston

"Reliability of Materials," Walter C Fish, '87, manager, Lynn Works, General Electric Co, Lynn, Mass

"A Consideration of Certain Limitations of Scientific Efficiency," Henry G Bradlee, '91, Stone & Webster, Boston

"Scientific Industrial Operation," Tracy Lyon, '85, assistant to first vice president, Westinghouse Electric & Mfg Co, Pittsburgh, Pa

"The Trend of Commercial Development Viewed from the Financial Standpoint," Charles Hayden, '90, banker, Boston

"Profitable Ethics," David Van Alstyne, '86, vice president, Allis Chalmers Co, Milwaukee, Wis

"The Natural Increase in the Ratio of Burden to Labor in Modern Manufacturing Processes," James B Stanwood, '75, vice president and engineer, Houston, Stanwood & Gamble, Co, Cincinnati

"Scientific Management of American Railways," Samuel M Felton, '73, president, Chicago Great Western R R, Chicago, Ill

SECTION D—RECENT INDUSTRIAL DEVELOPMENT

Chairman, Professor D C Jackson

"The Elimination of some Sources of Loss in a Large Producer gas Engine Plant," John G Callan, '96, electrical engineer, Arthur D Little, Inc, Boston

"Improvements in Efficiency of Electric Lighting Properties and what the Public Gains Thereby," William H Blood, Jr, '88, technical expert, Stone & Webster, Boston, Mass

"Advent of Illuminating Engineering," John S Codman, '93, electrical and illuminating engineer with the Holophane Co, Boston

"Development of Gasoline Engines," Joseph C Riley, '98, assistant professor of mechanical engineering, Massachusetts Institute of Technology, Boston

"The Progress of Electric Propulsion in Great Britain," Henry M. Hobart, '89, consulting engineer, London, England

"Mechanical Handling of Materials," Richard Devens, '88, manager eastern office, Brown Hoisting Machinery Co, New York City

"The General Solution for Alternating Current Networks," George A Campbell, '91, research engineer, American Telephone & Telegraph Co, New York City

"Electro chemistry and its Recent Industrial Development," Harry M Goodwin, '90, professor of physics and electro chemistry, Massachusetts Institute of Technology, Boston

"Mail Handling Machinery at the Pennsylvania Railroad Terminal and United States Post Office

at New York City," Julian E Woodwell, '96, consulting engineer, New York

"The Development of a System of Underground Pneumatic Tubes for the Transportation of United States Mail," B C Batcheller, '86, chief engineer, American Pneumatic Service Co, New York City

"The Continuous Cooling of Circulating Water used for Condensing Steam," Edward F Miller, professor of steam engineering, Massachusetts Institute of Technology, Boston

"Power Plant Betterment," H H Hunt, '89, Stone & Webster Management Association, Boston

"The Development of Economical Ore Dressing Systems," Frank E Shepard, '87, president, Denver Engineering Works, Denver, Colo

"Recent Developments in Bridge Construction," Frank P McKibben, professor of civil engineering, Lehigh University, South Bethlehem, Pa

"The Manufacture and Use of Asbestos Wood," Charles L Norton, '93, professor of heat measurements, Massachusetts Institute of Technology, Boston

"The Technics of Iron and Steel," Theodore W Robinson, '84, vice president, Illinois Steel Co, Chicago, Ill

SECTION E—PUBLIC HEALTH AND SANITATION

Chairman, Professor W T Sedgwick

"Profitable and Fruitless Lines of Endeavor in Public Health Work," Edwin O Jordan, '88, professor of bacteriology, University of Chicago, Chicago, Ill

"The Technical School Man in Public Health Work," Harry W Clark, '88, chief chemist, State Board of Health, Boston

"Present Status of Water Purification in the United States and the Part that the Massachusetts Institute of Technology has Played," George C Whipple, '89, consulting engineer, New York City

"The Pollution of Streams by Manufacturing Wastes," William S Johnson, '89, sanitary and hydraulic engineer, Boston

"Sewage Disposal with Respect to Offensive Odors," George W Fuller, '90, consulting hydraulic engineer and sanitary expert, New York

"The Food Inspection Chemist and his Work," Herman C Lythgoe, '96, analyst, State Board of Health, Boston

"The Life Saving Corps of the Technical School," Severance Burrage, '92, professor of sanitary science, Purdue University, Lafayette, Ind

"Factory Sanitation and Efficiency," C-E A Winslow, '98, associate professor of biology, College of City of New York, New York City

"A Review of the Work of the Sanitary Research Laboratory and Sewage Experiment Station of the Massachusetts Institute of Technology," Earle B Phelps, '99, consulting sanitary expert, New York City

"Bacteria and Decomposition," Simeon C Keith, Jr, '93, assistant professor of biology, Massachusetts Institute of Technology, Boston

SECTION F—ARCHITECTURE

Chairman, Professor F W Chandler

"Landscape Architecture, a Definition and a Brief Résumé of its Past and Present," Stephen Child, '88, landscape architect and consulting engineer, Boston and Santa Barbara

"Some Phases of Modern Architectural Practise," Walter H Kilham, '89, architect, Boston

"The Engineer and Architect Unite," Luzerne S Cowles, '97, assistant designing engineer, Boston Elevated Railway Co, Boston

"Mill Construction with Steel Frame and Tile Walls," John O DeWolf, '90, mill engineer, Boston

SCIENTIFIC NOTES AND NEWS

Sir J J Thomson, Cavendish professor of experimental physics in the University of Cambridge, and Dr D Hilbert, professor of mathematics at Gottingen, have been elected corresponding members of the Paris Academy of Sciences

The University of Edinburgh will confer its doctorate of laws on Mr Frank W Dyson, the astronomer royal, and on Dr Ernest Rutherford, professor of physics in the University of Manchester

The University of Aberdeen has conferred its LL D on Dr A R Cushny, professor of materia medica in the University of London, on Dr Arthur Keith, Hunterian professor of anatomy in the Royal College of Surgeons, and Major P A Macmahon, deputy warden of the standards.

Dean Liberty H Bailey, of the State School of Agriculture at Cornell University, has written to Governor Dix, of New York, expressing regret that he can not accept the appointment of state commissioner of agriculture

MR. ROBERT CUSHMAN MURPHY has been appointed curator of the division of mammals and birds in the Museum of the Brooklyn Institute of Arts and Sciences in place of George K. Cherrie, who recently resigned. Mr. Robert H. Rockwell has been appointed chief taxidermist of the same institution to fill the position left vacant by the death of Mr. Critchley.

J. W. TURRENTINE, Ph.D. (Cornell, 1908), instructor in physical and electrochemistry in Wesleyan University, has been appointed scientist in Soil Laboratory Investigation, Bureau of Soils, Washington, D. C.

MR. J. B. HILL, who joined the staff of the British Geological Survey in 1884, has just been appointed to the newly-created post of geological adviser to the local government board.

THE services which Dr. Lazarus Fletcher, F.R.S., has rendered to the Mineralogical Society during his twenty-one years' tenure of the office of general secretary have been recognized by the presentation to him of his portrait painted by Mr. Gerald Festus Kelly.

THE Tiedeman prize of the Senckenberg Natural History Society of Frankfort has been awarded to Dr. Richard Willstatter for his researches on chlorophil.

DR. R. HAMLYN-HARRIS has been appointed director of the Queensland Museum.

DR. EDMUND B. HUEY has resigned his position as clinical psychologist to the Illinois state institution for the feebleminded at Lincoln, Illinois, to continue clinical research at the Johns Hopkins Hospital and in the city of Baltimore.

PROFESSOR WM. B. ALWOOD, enological chemist, in the Bureau of Chemistry, Washington, D. C., sailed on April 13 for Gibraltar and will investigate viticultural conditions in Spain, Italy, France and Germany. He will also participate as a delegate in the International Agricultural Congress at Madrid and in the International Viticultural Congress at Montpellier. Professor Alwood is on the program for papers on the discovery of "Sucrose in American Grapes" and "On the Chemical Composition of American Grapes."

THE Laysan Island Expedition from the State University of Iowa sailed on April 5 from San Francisco on the U. S. Army Transport *Sherman*. The party consists of professor Homer R. Dill, in charge of the expedition, Mr. Charles A. Corwin, of Chicago, artist, and Messrs. Horace Young and Clarence Albright assistants. These men are to be stationed on the Island of Laysan in mid Pacific for a period of about two months, and are to furnish a detailed report to the U. S. Biological Survey, Department of Agriculture, regarding the famous bird rookeries of Laysan, with special reference to the effects of the raid made on them by Japanese feather hunters about two years ago. The island is a part of a "Bird Preserve" by proclamation of President Roosevelt, and the members of the expedition are appointed as game wardens during the period of their stay. The expedition is financed by friends of the State University of Iowa, and the party has permission to secure material for a cycloramic exhibition of the bird rookeries which is to be installed in the museum of natural history of the university.

MR. MAURITZ SAHLBERG, of Sweden, is on an extended visit to this country to study hydro-electric developments for the department of commerce of the Swedish government.

ON the evening of April 5, Professor G. W. Ritchey, astronomer of the Solar Observatory of the Carnegie Institution, delivered an illustrated lecture before the Indiana University chapter of Sigma Xi, on "Stellar Photography."

DR. ELIHU THOMPSON, of the General Electric Company, lectured on March 31 to the students of Throop Polytechnic Institute, Pasadena, Cal.

WE learn from *Nature* that it is proposed, in memory of the late Dr. Louis Olivier, founder of the *Revue générale des sciences*, to publish a book containing contributions from men of science and letters who knew M. Olivier. The volume is to appear next August for the anniversary of the death of M. Olivier,

and will be accompanied by a booklet containing his portrait, a biographical sketch and a bibliography of his works

TEN thousand dollars has been contributed to the University of Pennsylvania to establish a memorial to the late Dr J A Scott, adjunct professor of medicine in that institution This memorial will take the form of a fellowship for medical research

IT is proposed to erect in Amsterdam a monument to the memory of the late Professor van't Hoff

DR CHARLES A OLIVER, of Philadelphia, known for his contributions to ophthalmology, has died at the age of fifty-seven years

MR ARTHUR RAY MATHON, instructor in mathematics at Columbia University, died on April 13, at the age of thirty years

DR JAK M VAN BEMMELEN, emeritus professor of chemistry at Leyden, died on March 14 in his eighty-first year

THE paleontologist, Professor Joseph Lahusen, died in St Petersburg, on March 8, at the age of sixty-six years

PIETER CORNELIUS TOBIAS SNELLEN, the Dutch entomologist, has died at seventy-seven years of age

THE *Bulletin* of the American Mathematical Society gives the names and theses of candidates who received doctorates in mathematics from the German universities during the academic year 1909–10 They number 38, Leipzig leading with seven About fifteen doctorates in mathematics are given annually by the universities of the United States

THE Russell Sage Institute of Pathology, which was founded in 1907 when Mrs Sage gave $300,000 for pathological research work in connection with the hospitals and charitable institutions on Blackwell's Island, has resolved to terminate the agreement existing with the Public Charities Department

THE London *Times* states that at a meeting of the Paris Academy on April 3, Prince Albert, of Monaco, announced that he would shortly commission a new steamship, the *Hirondelle II*, to take the place of the *Princesse Alice II*, which had 12 scientific cruises to her credit He informed the academy that, thanks to a new dredging apparatus, interesting specimens of the denizens of the intermediate depths of the ocean had been secured The apparatus consisted of a net, which could be dragged at a speed of 15 kilometers an hour at any depth In 1910 the *Princesse Alice* had towed this appliance at a depth of 5,000 meters, and a dozen new kinds of fish had been brought to the surface in as many days Arrangements had likewise been made for taking instantaneous color photographs of the specimens as soon as they were hauled up out of the water

ACCORDING to *Nature* three expeditions from England will observe the total solar eclipse of April 28, on Varau, a small coral island of the Friendly Group They are as follows (1) A government expedition from the Solar Physics Observatory with Dr W J S Lockyer, in charge, and accompanied by Mr F K McClean, left London on February 3, with the necessary gear, and journeyed to Sydney by the Orient steamship *Otway* From there the instruments were transhipped to H M S *Encounter*, of the Australian Squadron, and the expedition started for the Friendly Islands on March 25 (2) An expedition from the Joint Permanent Eclipse Committee will be under the charge of Father A L Cortie, S J, from Stonyhurst Observatory, who will be assisted by Mr. W McKeon, S J, and Father E F Pigot, S J Father Cortie's expedition also travelled by the *Otway* from London, and proceeded to Varau on board the *Encounter* (3) A private expedition in charge of Mr J H Worthington, who has had a special equipment made for this eclipse

PERHAPS no other metal has been used in so great a variety of ways during so comparatively brief a history as has aluminum. It is a question whether the automobile industry would have made such a remarkable progress during the last decade without the accompanying development of the metallic aluminum industry, for very many of the castings used in the manufacture of motor cars are made from this light, rigid metal The use of aluminum in the recently born art of aviation is also of great popular interest, and here again the same

qualities of lightness and rigidity recommend it Aluminum is the most abundant of all the metals It is an essential constituent of all important rocks except sandstones and limestones It is found chiefly in the silicates such as the feldspars, micas, clays, etc , and as the hydroxide in the mineral bauxite, from which it is now produced on a commercial scale Its oxide makes up between 15 and 16 per cent of the earth's crust In spite of this great abundance the metal itself was, up to 1880, a chemical curiosity, and one of the early reports of the United States Geological Survey quotes it at $1 25 a Troy ounce—$15 a pound The reason for its rarity and high price was the lack of a commercial method of extracting it easily and cheaply from its chemical combination with oxygen, for which it has a remarkable affinity With the introduction of electrolytic processes the metal has now taken a high place among the commercial metals, and from a production of 83 pounds in 1883 its consumption amounted in 1909 to the enormous total of 34,210,000 pounds, valued at approximately 23 cents a pound for ingot metal

UNIVERSITY AND EDUCATIONAL NEWS

HARVARD UNIVERSITY has received the hundred thousand dollars required for the Wolcott Gibbs Memorial Laboratory which is to form the first building of the new chemical laboratories to be erected south of the university museum It is understood that half of the sum was given by Dr Morris Loeb and Mr James Loeb It is estimated that about $65,000 will be needed for the construction of the building The rest of the $100,000 will be used for maintenance

AT a stated meeting of the trustees of Princeton University on April 13, gifts amounting to more than $90,000 were announced

DR DANIEL K PEARSONS, the Chicago philanthropist, whose benefactions to the various colleges and benevolent institutions have exceeded $6,000,000, celebrated his ninety-first birthday on April 14 and marked the occasion by distributing $300,000, including $100,000 to Berea College, $25,000 to Deane College and $10,000 to McKendree College

THE North Carolina legislature at its last meeting appropriated to the University of North Carolina $200 000 for equipment and increased the appropriation for maintenance to $87,000 a year The trustees have decided to erect first a medical laboratory costing $50,000

As has been announced in SCIENCE a bill proposing one board of control for the three educational institutions of Kansas was vetoed recently by Governor Stubbs He had proposed to the legislature a commission form of government for the institutions, five members to take the place of the eighteen now acting as regents, but a bill was passed providing for a board of three, each to receive $2,500 a year, to give their whole time to the management of the State University at Lawrence, the State Normal School at Emporia and the State Agricultural College at Manhattan As these institutions have within their walls approximately seven thousand students, Governor Stubbs believed that one man competent to plan the educational and business program for each of them would be worth much more than $2,500 This opinion was confirmed when he attempted to fill the positions and found out that the present incumbents, serving for no salaries, would not agree to continue their services The leading educators of the country telegraphed to Governor Stubbs, in response to inquiries, that the one-board principle was advisable, but the methods about to be pursued by Kansas in adopting that system were faulty, particularly in the number of members proposed and the remuneration offered. The strongest opinions against the measure came from states where a similar plan is being tried or has in the past been tried Governor Stubbs did not care to take upon himself, he said, the responsibility for disorganizing the educational system of the state and therefore he vetoed the bill

GOVERNOR LEE CRUCE, of Oklahoma, has appointed a board of education consisting of six men, to take charge of all of the state educational and charitable institutions. This board

was ordered by the recent legislature, and succeeds the boards of regents of the university, the normal schools, the deaf and dumb school, the blind school, the girls' industrial school, the university preparatory schools, the various charitable institutions, etc., and also succeeds the former text book commission. Governor Cruce, in his address to the members of this board, said in part: "I regard this board as the most important public body which has ever been, or ever will be constituted in this state. This is a radical departure from established methods, and it is impossible for me to overstate the interest and anxiety I feel for the successful outcome of your labors. I want to say, with all the emphasis that I can command, that politics absolutely be eliminated from educational matters in Oklahoma—as thoroughly as church and state are now divorced. Members of this board may be removed for cause, and I should regard it as good and ample cause for removal if any member should permit political or personal motives to influence him in the employment or discharge of persons connected with the state schools, or in any other matters coming within the jurisdiction of this board."

AT its recent session the legislature of Kansas appropriated approximately one million dollars for the State Agricultural College at Manhattan for the next biennium. The funds provide for one wing of an agricultural building, with a detached laboratory for the cutting and curing of meats. The first wing of the new building is to cost $125,000. Two more wings are to be added as the money is appropriated, each complete in itself. The legislature also provided a special fund of $22,000 to complete the armory and gymnasium, which included literary society halls, swimming pools, and complete equipment for the whole; money for experiments in the western part of the state in cooperation with the federal government, for soil surveys, also in cooperation with the United States government, $5,000 a year; for experiments in producing improved wheat, corn and other crops, $7,500 a year. The college has this year approximately 2,500 students, more, it is said, than are enrolled in any similar institution in the world. The cost per student in this institution in 1910 was $107. Kansas, with a population of less than 1¾ millions, had, in 1910, more students in colleges than had Missouri, with more than 4 million population. Illinois, in its agricultural college and university combined, had 4,638 students in 1910. Kansas, with its agricultural college and university separate, had 4,608 students, thirty fewer than Illinois, which has 6 million population.

MR. ANDREW CARNEGIE has given $25,000 to the faculty of medical sciences of London for the section of a building to be devoted to pharmacology.

AS has been noted here M. Loutreuil bequeathed $500,000 to the University of Paris. The bequest is on condition that the provincial universities also shall benefit by the revenue which is to be devoted to the encouragement of scientific studies, the equipment of laboratories, the formation of a library and the foundation of additional lectureships on scientific subjects.

DR. LAJOS SCHLESINGER, of the University of Budapesth, has been called to the chair of mathematics in Giessen as successor of Dr. Moritz Pasch.

AT Princeton University Dr. H. N. Russell has been promoted to be professor of astronomy.

DISCUSSION AND CORRESPONDENCE

THE MEANING OF VITALISM

PROFESSOR RITTER's interesting address as vice-president of Section F of the American Association[1] makes manifest once more a difficulty which confronts every one who would discuss the question of vitalism: namely, the lack of either clear or generally accepted definitions of the terms ("vitalism" and "mechanism") used to designate the opposing doctrines under discussion. Professor Ritter himself is so sensible of this difficulty that he frankly gives up attempting any complete conformity to "lexicographical authority and historical usage," and simply puts forward

[1] SCIENCE, Vol. XXXIII., No. 847, March 17, 1911, pp. 437–441.

special definitions *ad hoc*, of his own formulation, as an indication of the particular doctrines with which he is for the time being concerned. This, of course, is a perfectly legitimate procedure, but even this wise precaution can free the ensuing discussion from irrelevancy and terminological confusion only upon three conditions: first, that the definition itself be unequivocal; second, that the writer subsequently use the term only in the sense defined; and third, that the sense given to it by his definition correspond to doctrines actually held by contemporary writers worth considering, and to the fundamental principles of those doctrines rather than to their adventitious details. I am not quite sure that the first two conditions are wholly fulfilled in Professor Ritter's discussion; his definition of vitalism seems to me diffuse and of rather elusive meaning, and it does not seem altogether clear that the vitalism with which some of his remarks deal is the vitalism defined. These, however, are merely questions of verbal consistency upon which it would be unprofitable to dilate. Of more material consequence is the third requirement, for if it be not fulfilled, the discussion, however clear and unambiguous, is unlikely to be pertinent to *the* controversy over vitalism, as an important contemporary issue. Do, then, Professor Ritter's definitions really expose the nerve of that issue? I am not convinced that they do. In order, however, to avoid a merely *ad hominem* argument, I should like to suggest another way of approaching the matter which seems to me more likely to expedite an ending of the controversy between mechanism and vitalism. I shall do so by indicating in the order of their logical priority what appear to be the three essential questions involved in the controversy, and the nature of the opposing views which may be, and have been, taken upon each of these questions.

1. The first question concerns the logical relation of the "laws" or generalizations of biology to those of other sciences. The mechanistic doctrine, whatever more it may imply, at least asserts that the explanations of organic processes can eventually be found in the laws of some more "fundamental" science whose generalizations are more comprehensive than those of biology, covering some (or all) inorganic phenomena, as well as organic. The full mechanistic program would be realized if biological laws could be shown to be special cases of chemical laws, these in turn of physical, and these finally of the laws of mechanics. Roux, for example, thus sets down the aspiration of the science of *Entwicklungsmechanik*: *Das organische Geschehen ... auf anorganische Wirkungsweisen zurückzuführen, es in solche Wirkungsweisen zu zerlegen, zu analysieren.* The vitalist, on the other hand, however much more he may assert, maintains at least the impossibility of this reduction of organic processes to the laws of the sciences of the inorganic. The first article of the creed of the recent defenders of vitalism, and perhaps the one article on which they are all agreed, is the principle of *Lebensautonomie*, which is thus formulated by von Hartmann: *Aus anorganischer Materie kann das Organische von selbst, d. h. nach anorganischer Gesetzlichkeit allein, nicht entstehen.*

But what precisely is the matter at issue here, and by what test, if it were available, could the issue be decided? In what would a *Zurückführung* of biology to chemistry or physics consist? It would consist in showing that a given organic process A can be subsumed under and *deduced from* a given generalization, B, of the more "fundamental" science. The proof of the autonomy of biology, on the other hand, would consist in showing that there are modes of action characteristic of matter when organized into a living body which can never be deduced from any law that describes any modes of action of inorganic matter. But here an explanation about deducibility is needful, since the notion has been somewhat confused in some recent discussions. From *no* general law alone, even if it is known to be true, can *any* more special law, or individual phenomenon, be deduced; and this follows from the very notion of a scientific law. For such laws are generalized statements of certain constant correlations *between two or more variables*, and in order

that from the law anything more specific shall be predicted or deduced, it is necessary that there be given empirically certain information concerning at least one of the variables. Without some empirical knowledge concerning the motions or masses of some bodies, nothing could be inferred about bodies from the law of gravitation For this additional empirical knowledge about the actual values of the variables the laws themselves, if properly formulated, expressly call But the undeducibility of biological from other laws, which the vitalist asserts, is not simply the undeducibility due to a lack of the specific empirical information called for by those other laws What the vitalist maintains is that, even given a complete knowledge *both* of all the laws of motion of inorganic particles and of the actual configuration of the particles composing a living body at a given cross-section of time, you could not from such knowledge deduce what the motion of the particles, and the consequent action of the living body, would be What he asserts primarily, in short, is the doctrine of the logical discontinuity, at certain points, of scientific laws This discontinuity does not necessarily imply any breach of the principle of causal uniformity Whenever a number of particles acting in accordance with one set of laws (*e g*, of mechanics) are brought into a certain configuration, they may conceivably thereafter take to moving in ways not correctly described by the aforesaid laws, if so, the conditions under which the shift from one mode of action (*i e*, action of which a correct generalized description is given by the one set of laws) to the other mode takes place are uniform, and a new law may be formulated setting forth that very uniformity of discontinuity Again, such a view would not, in itself, deny that the behavior of organisms is a function of the number and configuration of the material particles composing them

Such a doctrine of the autonomy of a given science might conceivably be applied to other sciences besides biology. It might be held, for example, that chemistry is similarly autonomous with respect to physics, or psychology with respect to biology It might, again, be maintained that the real point of discontinuity comes, not where chemistry connects with biology, but rather where physics connects with chemistry—biological phenomena being in themselves theoretically inferrible from chemical laws, when chemical laws are more adequately known I do not now inquire whether any such views are plausible or not, I merely point out that vitalism is first of all a special case of what might be called scientific autonomism, or logical pluralism Mechanism, meanwhile, asserts the possibility of an eventual unification of scientific laws Between the two is possible an agnostic position, based upon the observation that both sides agree that no such unification is yet achieved, and that both have some difficulty in proving either that it must be or that it can not be achieved in the future

In so much of vitalism, however, there appears to be nothing that can properly be called "mystical" or "transcendental," nor anything that can especially profitably be regarded as a survival of primitive animism

2 There is, however, a doctrine which goes beyond this mere assertion of organic autonomy, and declares that (in part) the action of living bodies *is not strictly a function of the number and spatial configuration of the particles composing them at any given instant* In other words, organisms not only have unique laws of their own, but these laws can not even be stated in terms of the number and arrangement of the organism's physical components Not all who call themselves, or have been called, vitalists assert so much as this, but the neo-vitalism of Driesch maintains precisely this view, and endeavors to support it by definite empirical evidence Driesch seeks in the phenomena of regulation, regeneration and conscious behavior, evidence for the assertion that the composition (physical and chemical) of an organism, on the one hand, and its morphogenesis and activity, on the other, are (to some extent) independent variables With a radical variation in composition—*e g*, after the elimination of half the blastomeres at a certain stage of develop-

ment in certain embryos—you may, he contends, get an identical resultant form (except with respect to size). About the experimental facts there can be no question, though there appears to me to be a fairly evident flaw, of a purely logical sort, in the inference which Driesch draws from them. I do not, however, wish here to discuss the truth of vitalism, but merely to elucidate its import. But even for the latter purpose it is important to note that Driesch's vitalism by no means maintains that the specific properties or activities of organisms are not functions of *any* antecedent material or physico-chemical configuration. Whales do not develop from sea-urchin's eggs, nor does the unfertilized egg develop at all. Always you must first have given a definite mechanism, at the beginning of any morphogenetic or other vital process, and for different products you must have different original mechanisms. All that Driesch maintains is that such a process once started continues towards its normal consummation even if, after the start, some of the usual machinery instrumental to that consummation is lost and the rest has to redistribute and redifferentiate itself in order to keep things moving in the customary manner. In short, even the processes in which Driesch finds the independent variability of the physical mechanism of a living body and its physiological processes exemplified, still, even for him, have perfectly definite, perceptible and experimentally ascertainable constant antecedents, if you go back to an early enough stage in the given sequence of processes.

3. The fundamental questions concerning vitalism are the first two questions. Can some biological phenomena be shown to be, in the sense defined, autonomous? and can some of them even be shown not to be functions of any fixed configuration of material parts existing in the organism or cell at the moments at which the phenomena take place? Now, one might conceivably answer one or both of these questions in the affirmative, and stop there. Such would be the procedure of a convinced vitalist who had caught the spirit of scientific positivism. But most vitalists, undoubtedly, are not of a positivistic temper, and they have accordingly often gone on to account for the asserted peculiarity or uniqueness of organic *processes* by hypostatizing special *forces* or agents as causes of these peculiar modes of action. Such hypostases have been made in three different fashions by three recent schools of biological philosophers, of which the first would apparently refuse to be called vitalistic. The qualitative *Energetiker* (*e. g.*, Ostwald, Rignano) in so far as they set up as a real entity a specific vital or neural form of energy, having properties and modes of action not characteristic of energy in any other of its transformations, seem to imply both the autonomy of organic phenomena and the need of postulating a special dynamic background for these phenomena. The psycho-vitalists (who are indeed biological animists), such as Pauly, Francé, Strecker, find the cause of the unique modes of physical behavior distinctive of organisms in a *seelisches Innenleben*, a rudimentary form of consciousness and of purposive action, ascribed to even the simplest living things. And Driesch and Reinke and their followers, in order to explain how organisms can, as these biologists believe, pursue their typical ends even after a considerable modification or partial destruction of their usual machinery, postulate "entelechies" or "dominants" having the power, so to say, to take command even of a disabled organic ship and steer it (under certain conditions) to its destined port.

Now, it is doubtless in these vitalistic hypostases that Professor Ritter finds the trait which makes vitalism resemble savage animism. I wish, therefore, to insist upon two considerations in this connection. In the first place, as I have tried to show, the question whether it is worth while to set up such hypostases, not open to direct observation, is wholly subsidiary to questions 1 and 2, which have to do with potentially ascertainable facts concerning the *laws* of organic processes. If the verdict upon either of those questions goes in favor of the vitalist's contention, the main issue is settled. Whether, vitalism being assumed, it would be worth while to postulate

hypothetical and imperceptible forces or entities to account for the perceptible facts, is essentially a question of scientific convenience. The presumption, surely, is in favor of the positivistic method, which is content to correlate the observable data without going behind them. Yet it must be confessed that it is not by such avoidance of hypotheses concerning imperceptible causes or substances that physics and chemistry have achieved their best results. And the precedent of those sciences might be plausibly (though, I think, unwisely) made, by one convinced of the truth of the vitalistic answer to one or the other of the first two questions, an excuse for not taking his vitalism positivistically or pragmatically. In any case, these hypothetical "forces" or causes would constitute elaborations or embellishments of his doctrine, they would not constitute the basis or the irreducible minimum of it.

A word in conclusion about the position of Bergson, of which Professor Ritter speaks with cordial approval. Bergson holds the doctrine of organic autonomy in a special and a somewhat extreme form. Inorganic and organic processes manifest, in his opinion, radically dissimilar modes of causality. "The present state of an inanimate body depends exclusively upon what took place at the preceding instant. The position of the material points of a system is determined by the position of the same points at the immediately antecedent moment. In other words, the laws which control unorganized matter can be expressed in differential equations in which *time* (in the mathematician's sense) plays the part of an independent variable." This, Bergson insists, is not true of living bodies, their present state does *not* "find its complete explanation in the immediately anterior state." We must absolutely give up "the idea that the living body could be subjected by some superhuman calculator to the same mathematical treatment as that which is applied to our solar system." The "creative" efficacy of organic evolution is shown, for Bergson, precisely in the impossibility of deriving from even the most complete knowledge of the configuration of the components of an organism at a given moment, and of all the "laws" which have been disclosed up to that moment, any absolutely complete and certain knowledge of the future condition and action of that organism. Bergson, moreover, does not stop with this anti-mechanistic view of the actual behavior of organisms, he suggests an explanation for what he conceives to be the facts. And his explanation, though rather elusive, approximates that given by the psycho-vitalists. The neo-Lamarckians, he declares, are right in referring organic evolution to "a cause of the psychological order," though they apprehend this too narrowly. The conception of "effort should be taken in a sense more profound, a sense even more psychological, than any neo-Lamarckian has supposed." It is true that Bergson does not seem to call his doctrine vitalism, and that he speaks in criticism of the vitalism of certain other writers. But it seems to me that any dogmatic (*i. e.*, not merely provisional or agnostic) anti-mechanism in biology should be called vitalism. In other words, the doctrine which it appears to me to be linguistically most convenient to designate by that name is the doctrine of organic autonomy in its biological application, the assertion of an essential logical discontinuity between the "laws" or modes of action of matter dealt with by biology and the "laws" of all the sciences of the inorganic. And in this sense, of course, Bergson is an unmistakable and a radical vitalist. It would certainly be paradoxical to withhold the name from a writer who does not hesitate to say that the "parts of an organized machine do not correspond to parts of the work of organization, since *the materiality of this machine does not represent a sum of means employed, but a sum of obstacles avoided*" by the *élan vital* in its form-creating activity.

PRODUCTIVITY OF SOILS

The discussion of the "Secular Maintenance of Soils" by Professor Chamberlin

before the Geological Club of the University of Chicago aimed at so fundamental and comprehensive a presentation of the subject and the report of it by himself in SCIENCE, February 10, p 225, is cast with such pedagogic effect that it is much to be regretted that a goodly part of the discussion was not incorporated with the report, as without this some statements are likely to be interpreted in a way widely at variance with authentic data and hence in a way to be misleading

Although most that is said is undisputed, this presentation in fifty-three terse statements of somewhat unusual form is certain to convey to younger students of the subject the impression that each and all of these phases of the great problem of soil productivity have been brought into the clear light of science and are here set out in proper order This is, of course, not true and not intended to be so understood but the great confidence accorded to the author's utterances is in danger of leading to the acceptance of his suggestions and beliefs as established knowledge, and to assigning to minor factors an importance far too great

The importance of capillarity in supplying potassium and phosphorus to crops, emphasized by the figures which are cited, will be understood as being much greater than can be the case Indeed, instead of the "capillary cycle" and the "plant cycle" tending on the whole to the concentration of potassium and phosphorus toward the surface of the soil contributing to "secular maintenance," as is implied, quite the reverse tendency is the case, as may be seen from a comparison of the composition of soils and of rocks We cite the complete analyses of 27 soils given by Hopkins[1] in the form of mean values for three depths

In this series 74 per cent of the cases in the second depth have the potassium higher than in the surface soil, and 59 per cent of the cases in the third depth have the content higher than in the surface sample The larger amount of phosphorus compounds in the surface soil is not a case of concentration due to the action of either or both cycles named, but has occurred in spite of them and is less than it would have been because of their action The most pronounced effect of both "cycles" is to leave soluble ingredients upon or above the surface of the soil whence they are transported to the sea by both surface drainage and wind action, the loss in this way being materially greater than the supply by capillarity to the root zone

Depth	Phosphorus (P) lbs per million	Potassium (K) lbs per million
0 to 6⅔ inches	581	16,376
6⅔ to 20 inches	455	16,649
20 to 40 inches	488	16,936

	Igneous Rock	Sedimentary rock Shale	Sand stone	Lime-stone
	Pounds per million			
Potassium	24,400	26,951	10,959	2,740
Phosphorus	1,100	7,426	3,404	1,747

The phosphorus content[2] of all rocks is seen to be higher than that of soils, and the higher content of sedimentary rocks will not be ascribed to either capillary or plant action, but to other processes named in the article It must of course require a positive addition of plant food elements to cultivated soils, in amounts equal to or greater than all removals, to perpetuate indefinitely uniform or increasing productivity

Studies like those of Professor Whitson[3] of phosphorus in cultivated and virgin soils indicate, in the case cited, an average loss of P_2O_5 during about sixty years, of 1,255 pounds per acre, from the cultivated soil, and in but three of the nine comparisons was the loss less than that which would be assigned to removal by crops It may fairly be questioned whether this difference is due entirely to greater loss from the cropped soils, but it

[1] "Soil Fertility and Permanent Agriculture," pp 82–87

[2] "Data of Geochemistry," Bull No 330, U S Geol Survey, pp 26–27

[3] Research Bulletin No 2, University of Wisconsin Agr Expt Station

will hardly be urged that it is even chiefly due to capillary and plant concentration such as might prevail over large areas like the United States At least the projection of such a rate of concentration through any material period forward or backward would point to very unusual if not impossible conditions

If it be true that 1,200,000 tons of PO_4 are lost annually from the soil of the whole United States by drainage into the sea and that capillary water is carrying toward the surface 18,000,000 to 40,000,000 tons, there would be a total mean movement of 30,200,000 tons of PO_4 or 9,800,000 tons of phosphorus A yearly removal at this rate maintained for 10,000 years would require more phosphorus than is carried in 10 5 feet of igneous rock, assuming 200 pounds as the weight of a cubic foot and Clark's value cited above, and all of the phosphorus carried in 40 feet of soil weighing 4,000,000 pounds per acre-foot, containing 581 parts per million of phosphorus A combined chemical and mechanical erosion which would remove 40 feet in 10,000 years, from the United States, would have to exceed one inch in 21 years

It appears to be overlooked, in making the estimates, that capillary sweeping is very often and strongly downward as well as upward, and also that a large proportion, probably more than three-fourths of the rainfall, not removed in the runoff, never penetrates the soil beyond a depth of two feet and should not, therefore, be used as a measure of surfaceward movement of plant food below that depth We have measured the combined capillary and internal-evaporation-movement out of the 5- to 10-foot depth into the 0- to 5-foot depth in four instances, two of which were a clay loam and two a sandy loam soil. The measurement was continuous through 314 days under a summer temperature Under the most favorable conditions for upward movement water was carried from the 5- to 10-foot zone into the 0- to 5-foot zone at the rate of three pounds per square foot during the 314 days, where the surface was continuously firm, while under a 2-inch earth mulch the movement was 2 2 pounds In the sandy loam the movement out of the 5- to 10-foot zone into the 0- to 5-foot zone was less than 8 pounds in 314 days The annual combined upward movement from the 5- to 10-foot zone into the 0- to 5-foot zone, at the most rapid rate, was 7 inch in the clay loam and 17 inch in the sandy loam

Assuming a soil solution containing 20 parts per million of PO_4, the total phosphorus which might thus be added to the surface five feet from the five feet below, would be but 1 to 25 pound per acre annually and even these values we regard materially too high for average conditions, although they show a rate less than one fifth that of the estimate cited by Chamberlin It is true that the capillary and plant "cycles" are agencies which, at the time, assist in the utilization of plant food substances, but they primarily accelerate their waste and should not therefore be reckoned as "efficient factors" of secular maintenance of soil productivity

We quite agree that the Mongolian races have "demonstrated one mode of effective secular maintenance of the soil productivity," but we fail to see that it is "closely analogous to the natural method of the geologic ages" Our observations bring the conviction that they return to their fields, year by year, a full measure of all potassium and phosphorus removed with their crops, that their cultural methods very largely reduce losses by both physical and chemical erosion, and that they secure a very high efficiency for the plant food used by the crops All human and animal excreta and all fuel ashes of country and city are universally applied to the cultivated fields. Enormous quantities of bean, rape seed, cotton seed and peanut oil cake are used as fertilizers annually and an enormous tonnage of canal, reservoir and river mud is also applied, even to the extent of 70 to 100 tons per acre in some instances, as single dressings which must carry to the fields not less than 100 to 150 pounds of phosphorus Then their very extensive practise of irrigation adds, with the silt and soluble plant food carried in the water, quite as much fertility as is removed by leaching, and all irrigated areas are placed

under conditions which practically eliminate surface erosion Both canal and reservoir mud, together with soil and subsoil, are fermented with organic matter to be used as fertilizers to an extent which would appear to western nations impossible Indeed it appears probable that as much labor and time are spent in specific fertilization of the fields as in seeding and harvesting the crops

While these people, so far as we can learn, have never used rock phosphates or potash salts taken from mines, as western nations are doing in recent years, they have in effect done so to a remarkable extent through their home manufacture with their compost methods So far as we could discover they have nowhere developed or applied systems of tillage looking specifically toward physical amelioration, as such, for their soils but they have practised the culture of legumes as a source of nitrogen very systematically, persistently and extensively Feed and water the crops is written on every field in China and Japan Japan is now beginning to import notable amounts of commercial fertilizers and during the years 1906 to 1908 the total import of all kinds aggregated 1,427,658 tons, with a cash value of $55,423,304 and all applied to about 21,000 square miles of tilled land, constituting a tax of more than a dollar per capita for the entire population, and this is paying for an addition to an already enormously large yearly fertilization

But the one factor which is probably equal in importance to all others is the extreme personal attention and care bestowed upon the crops, made possible and necessitated by the dense population and increasingly smaller holdings But this has not and can not supplant their supplemental irrigation and their plant feeding except through a smaller annual output It must be this factor coupled with the increasing larger return to the fields of plant food which has given rise to the increase in yield during recent years in this country and in Europe, to which attention has been called It is clear that such increase may well be coincident with a decreasing plant-food content in soils of the stronger type and for the simple reason that great care may augment the rate of production of the plant-food content of film moisture for a time, with a decreasing content of the basal food elements That the oldest and most densely settled countries should show marked increase in yield is to be expected, for here is where better care pays best, where it is compelled and where it is more readily made possible because of the denser population But it should not be ignored that the countries named are those which are largely importing feeding stuffs and fertilizers which immediately or ultimately find place in the soil, and that those who purchase and apply these have faith that they are indispensable adjuncts to better cultural methods, improved varieties and more sanitary conditions

There were imported into the United Kingdom in 1885, 282,960 tons of oil cakes, 64,387 tons of bones and fish, 25,258 tons of guano, and 238,572 tons of mineral phosphates In addition, some 300,000 tons of Thomas slag are manufactured annually and largely used at home During 1861–65 there was a mean annual importation of 1,277,778 tons of grains and beans, besides wheat During 1901–05 importation had increased to an annual mean of 4,641,201 tons A mean of these values may be taken, together with the fertilizers named, as a low measure of the annual importation of plant-food substances into the United Kingdom during the past twenty or thirty years

As a rough approximation, it may be said that 2,000 pounds of the products named will contain

	N lbs	P lbs	K lbs
Oil cakes	120	18 8	30
Bones and fish	80	170	
Guano	70	170	
Mineral phosphates		250	
Thomas slag		160	
Grains and beans	50	8	12

The arable lands of the United Kingdom aggregate 19,528,000 acres and there are 28,267,000 acres of permanent pasture.

On the basis of the amounts named the

annual importation of the three plant-food elements, including that in 150,000 tons of Thomas slag, would be

	N tons	P tons	K tons
In oil cakes	16,977	2,660	4,244
In bones and fish	2,575	5,472	
In guano	884	2,147	
In mineral phosphates		29,821	
In Thomas slag		12,000	
In grains	73,987	11,838	17,757
Total	94,423	63,938	22,001

To these amounts should be added the heavy importations of nitrate of soda and of potash salts

The phosphorus content of these importations is sufficient to apply 6 54 pounds to each acre of arable land in the United Kingdom and this amount is all that is carried in the grain and straw of 20 bushels of wheat During the twelve years preceding 1906 there was an importation of potash salts sufficient to carry 99,426 tons of potassium, which, added to the above, aggregates enough for 13 pounds per acre of the arable land Through more than a century increasingly larger importations of fertilizers and feeding stuffs have been going into all of the countries of western Europe These annual additions of soluble plant food elements to the film moisture and to the interior of the soil granules can not fail to exert cumulative effects upon both microscopic and higher plant life, which together must react upon yields continuing their increase until available soil moisture and then standing room become the limiting factors

The increase in yield in the United States to which attention has been called is certainly associated with the importation of feeding stuffs and fertilizers, and while better cultural methods, better seed, better strains and fuller control of fungus diseases are responsible for some of these increases, the addition of plant food must play a large part now in the older states, especially in the North and South Atlantic groups where fertilization has been so long and so extensively practised In the northern group, $15,641,995 and in the southern, $22,732,670 were paid for fertilizers in 1899 and applied to less than 24,683,365 and 29,194,361 acres, respectively, the amount of land in all crops that year. To give expression to these figures in terms of plant-food elements and crop yields, the mean value and composition of twelve "complete"[4] fertilizers may be used, worth $23 per ton and containing 33 pounds of N and K and 88 pounds of P On this basis the fertilizer purchased would contain sufficient phosphorus for 2 42 pounds for every acre under crop in the North Atlantic states and for 2 98 pounds in the South Atlantic states These are the amounts of phosphorus contained in the grain and straw of 7 5 bushels of wheat and 10 5 bushels of corn in the first case and in the second case, 9 31 bushels of wheat and 13 0 bushels of corn But in the most thickly settled states the amounts of fertilizer used are much above the average, Rhode Island using sufficient to carry 10 2 pounds of phosphorus to each acre in crop, Connecticut, sufficient for 6 5 pounds, New Jersey, for 6 39 pounds, Massachusetts, for 6 37 pounds, while the District of Columbia is credited with fertilizers sufficient for 26 pounds of phosphorus and of 10 pounds of potassium per acre in crop, added to her cultivated soils each year

There never has been doubt regarding the truth embodied in the statement, "that therefore there must be some efficient natural process for the maintenance of soils," but because of its association with other statements there is danger that it may be taken explicitly to mean, that therefore there must be some efficient natural process for the maintenance of soil productivity capable of sustaining, in the United States, 2,000 million people with relatively little greater effort at curtailment of waste or of return of essentials to the soil than is now practised here If all that the Chinese and Japanese farmers are doing, and for centuries have felt compelled to do, are to be included in the "some efficient process," then all danger of misleading will be removed, for there has long been more applied science in the agriculture of "oriental experi

[4] Hopkins, "Soil Fertility and Permanent Agriculture," p 157

ence" than has yet been explained or suggested by "western scientific research"

It never can be too strongly emphasized that, granting suitable climatic and physical soil condition, the fundamental of crop production is crop feeding, and that crop hunger (and thirst) has been the prime condition determining reduced yield oftener than any other These have been the tenets of practical men through all the past and are likely to remain so to the end Disease, parasitism, phagocytism, degeneration of seed, toxic substances or what not may at times reduce yields and the advance of knowledge which shall make it possible to diagnose these cases and apply the proper remedy, for each will augment the efficiency of plant food but make the demands for it greater nearly in proportion to increase of yield, and will accelerate soil exhaustion where nature or man makes inadequate return

It is difficult to see on what basis of knowledge one may contend that the increase in the productivity of soils of western Europe, referred to as occurring in recent years, has been due to improvements along any of these minor lines rather than to better physical soil condition and to the increasing application of the three most essential plant-food elements which have certainly been coincident with these increases of yield, and even more difficult does the case become when referred to the long and high maintenance of soil productivity in China where plant feeding has been the heaviest burden of the people

F H KING

MADISON, WIS

A KINETIC THEORY OF GRAVITATION

TO THE EDITOR OF SCIENCE:

Imagine a pound weight of iron raised from the surface of the earth to a point near the moon, the point so chosen that the opposing attraction of the earth and the moon shall exactly balance each other In the surface of the earth the pound-weight had some so called "potential energy of position" because it was capable of falling into a pit but in its new position near the moon this potential energy has disappeared entirely, the pound-weight, left free to move, remains stationary We can not believe that the whole or any part of it [the energy] has been annihilated it must, in some form, be resident somewhere I believe it was absorbed by, and is now resident in, the ether through which the weight was raised Conversely if this be true, a falling body must acquire its energy from the ether through which it falls"[1]

Since the ether is as yet a hypothetical substance, postulated to explain certain physical phenomena, it may be allowable in discussing some phenomena to postulate its non-existence We do not know that if the ether were non-existent and only an imaginary substance, that gravitation would also be non-existent Assuming the non-existence of ether, but gravity acting as usual, would not the pound-weight act just as is described by Dr Brush?

Consider a simple case A ball weighing one pound is lifted five feet from the floor, and placed on a shelf It has a potential energy of five foot-pounds, with reference to the floor, but it can not exert this energy, or convert it into kinetic energy, for it is prevented by the shelf So if the ball is raised to the point near the moon, it has 20,000,000 foot-pounds of potential energy, referred to the earth, and this energy could be made kinetic, if the body were "free to move," which it is not, it is restrained by the attraction of the moon, just as it was restrained by the shelf Suppose the ball is of iron, and that on being raised five feet it comes within the field of attraction of an electromagnet which attracts it and prevents it falling to the floor It has five foot-pounds of potential energy, just as it had on the shelf, but it is for the time being unavailable Let the current which actuates the electromagnet be interrupted for a fraction of a second, the ball begins to fall and the potential energy becomes kinetic In neither of these cases has the potential energy "disappeared entirely," it has only been rendered unavailable by the attraction of the moon or the electromagnet, or by the shelf It has not been annihilated nor is it "resident in the ether"

[1] Extracts from an article, "Kinetic Theory of Gravitation," by Charles B Brush, SCIENCE, March 10, 1911

The ball, the earth and the moon are portions of matter, one of the fundamental entities, or primary concepts (defining concept as that of which the mind thinks, and not an action of the mind). Gravitational attraction, a force, whether a push or a pull, is also a fundamental entity. Energy, velocity, work, etc., are complex concepts, or mathematical expressions, involving two or more simple concepts, such as, matter, space, time and force, besides the concepts of condition, such as direction, relative position and availability. The potential energy of the ball on the shelf is not merely five foot-pounds, it is five foot-pounds relative to the position of the floor, and it is not available until it is rolled off the shelf.

Consider a one-pound ball held in the hand five feet above the floor of a railroad car which is traveling eastward at the rate of 32 feet per second. It has 5 foot-pounds of potential energy and zero kinetic energy relative to the floor of the car, and $\frac{1}{2}MV^2 = 16$ foot-pounds of kinetic energy relative to the earth. If it is thrown westward at the same velocity that the car is moving eastward, it has zero velocity and zero kinetic energy relative to the earth, but 16 foot-pounds of kinetic energy relative to the car, and it is capable of breaking the window in the door of the car if thrown against it.

If Dr. Brush's kinetic theory of gravitation depends on the hypothesis that the potential energy of a body raised from the earth's surface and held by the attraction of the moon (or of a magnet) disappears entirely and becomes resident in the ether, it is not likely to meet with acceptance.

There seems to be another weak point in his theory, viz., he assumes that the long radiant waves of ether, the hypothetical cause of gravitation, "pass freely through all bodies," and yet that they cast a "shadow." These two ideas seem to be inconsistent. A perfectly transparent glass plate casts no shadow of light when rays of light pass freely through it.

MONTCLAIR, N. J.,
April 3, 1911

WHAT IS THE GENOTYPE OF X-US JONES, 1900, BASED UPON A SPECIES ERRONEOUSLY DETERMINED AS ALBUS SMITH, 1890?

Statement of Case.—Jones proposes the new genus *X-us*, 1900, type species *albus* Smith, 1890.

It later develops that *albus* Smith, 1890, as determined by Jones, 1900, is an erroneous determination.

What is the genotype of *X-us*, 1900, *albus* Smith, 1890, or the form erroneously identified by Jones as *albus* in 1900?

Discussion.—The nomenclatorial problem expressed in the caption of this note is solved in two diametrically opposite ways by different authors.

Some writers maintain that the original *albus* Smith, 1890, is the genotype, while others maintain that the genotype is represented by the species actually studied by Jones and misdetermined as *albus* Smith.

Cases of this general nature have given rise to considerable confusion in nomenclature, and several such cases have been referred to the International Commission on Nomenclature for opinion.

At the last meeting of the commission, the principles involved came up for discussion, but it was impossible to reach a unanimous agreement. On account of the differences of opinion, the secretary was instructed to make a careful study of a number of cases, and to report upon the same to the commission.

It is not difficult to foresee that no matter how the cases are finally decided, great dissatisfaction will arise among zoologists because the opinion rendered is not the direct opposite of what it eventually will be.

Recognizing that this is one of the most difficult cases that has ever been submitted to the commission, and recognizing the fact that regardless of our action we shall probably be criticized more on basis of our decision on this case than because of any other opinion that we have rendered, I am desirous of studying at least one hundred cases if possible, that

would come under such a ruling, before my report is formulated

In view of the foregoing premises, I respectfully request zoologists in different groups to call my attention to as many instances of this kind as possible, with which they are acquainted in their different specialties Further, since the arguments on both sides of the problem appear to be almost equally valid, it does not seem impossible that the final decision will have to be based upon an arbitrary choice between the two possible rulings, and on this account I am desirous of obtaining all possible arguments on both sides as they occur to different zoologists, and also any personal views based upon convenience or inconvenience, or other grounds, which may be held by different colleagues

I will hold the case open at least until September 1, for the presentation of arguments by any persons who may desire to submit their views

C W STILES,
Secretary of the Commission

April 1, 1911

SCIENTIFIC BOOKS

Diseases of Economic Plants By F L STEVENS, Ph D, and J G HALL, M A New York, The Macmillan Co 1910 Pp 313, 214 figures $2 00 net

The authors of this work have sought to produce a book on plant pathology "for those who wish to recognize and treat diseases without the burden of long study as to their causes" To this end "technical discussion is avoided in so far as is possible," and "no consideration is given to the causal organism except as it is conspicuous enough to be of service in diagnosis, or exhibits peculiarities, knowledge of which may be of use in prophylaxis" Non-parasitic diseases are omitted, except a few of the most conspicuous

The volume opens with short chapters on the history of plant pathology, the damage done by plant diseases, their symptoms, prevention or cure, public plant sanitation, fungicides, spraying machinery, cost of spraying, profits from spraying, soil disinfection and general diseases.

The greater part is given to brief descriptions of plant diseases due to bacteria or fungi with suggestions regarding their prevention or cure For this purpose a grouping by hosts is adopted, viz, pomaceous fruits, drupaceous fruits, small fruits, tropical fruits, vegetable and field crops, cereals, forage crops, trees and timber and ornamental plants This is a commendable feature for a practical reference book as some such classification is much to be preferred to an arrangement according to the botanical relationship of the parasite

To present in a popular way a highly technical subject and to retain accuracy and thoroughness is a much harder task than writing for professional readers Diverse opinion exists as to the most effective method of presenting such a subject It is, therefore, to be expected that many readers will differ with our authors Their attention will first be arrested by the general use of *ose* as an ending for the generic name of the causal fungus to form a common name for the disease Decay due to blue mold becomes "penicilliose", dry rot of sweet potatoes, "lasiodiplodiose", wilt of cotton, "fusariose" etc There are many arguments against such names, and it does not seem wise to attempt to introduce them into a popular book before they have been accepted by plant pathologists

Some readers will not approve the omission of all technical details relating to the nature and life history of fungi, holding them to be as essential to pathology as mathematics to a treatise on engineering The short chapter on fungi in the appendix is not adequate nor is it correlated with the chapter on pathology

It is to be regretted that it was found necessary to limit the book to diseases due to fungi and bacteria, especially since the causes of diseases are not given prominence in the text The lay reader will be confused by the omission of the physiological fruit spot of the apple, while the similar but less important fungus fruit spot is discussed. Potato tipburn is given four lines while the no more important potato scab is allotted four pages of text The wilt and dieback of the orange are omitted as is the curly top of beet, one of the

two most important maladies of that crop That the viewpoint of the author is that of parasitology rather than pathology is further shown by the omission of any discussion of the physiology of disease The very brief appendix chapter on physiology has no relation to the rest of the book

From the standpoint of the lay reader it is feared that the space devoted to remedial measures is in most cases not sufficient, nor the recommendations as definite and specific as the needs of practise require

The large number of minor diseases mentioned without adequate description will also confuse the inexperienced student

Some more serious errors occur The reviewer knows of no warrant for the statement on page 445 that *Microsphæra alni* practically destroys the pecan crop in the south in certain years This fungus is one of the least harmful of the pecan parasites Stigmonose of carnation is not mentioned while there is a reference to a more obscure bacterial disease The discussion of mosaic disease of tobacco and tomato would be cleared by including Woods's results[1]

Absurdly large losses are attributed to cotton anthracnose in Georgia, and the injury to tomatoes from *Phytophthora* is overstated The description of Bordeaux injury is incorrect, as is also the statement that blossoms are killed and the lives of bees endangered by spraying with Bordeaux

All workers in plant pathology should possess this book and it will be useful to farmers, fruit growers and all who are interested in growing plants There has long been urgent need for a treatise on American plant diseases adapted to general readers, in which the widely scattered and often unobtainable recent publications should be summarized. This book is intended to meet this need

W A ORTON

Preliminary Report on the Peat Deposits of Florida By ROLAND M HARPER Third Ann Rept Fla Geol Surv, 1910, pp 197–375, pl 16–28, tf 17–30

[1] Bulletin 18, Bureau of Plant Industry, 1902

The state of Florida because of its flatness, its abundant ponds, lakes and swamps, its ample, well-distributed rainfall and the absence of sediment-laden streams, affords exceptionally favorable conditions for the formation of peat, and the present report is a monumental disproof of that ancient and persistent fallacy that peat is formed only in high latitudes

For purposes of discussion the state is divided by the author into fourteen more or less natural divisions based chiefly upon topography and vegetation, and these are shown on a sketch map The varied swamps of the state are elaborately classified, more than thirty types being enumerated and described in more or less detail The more common plants of each are listed in the order of their abundance

A few pages are devoted to fossil peat Numerous analyses of peat samples are given and there is a chapter upon the utilization of peat This is followed by a reliable systematic catalogue of Florida peat-forming plants and the report is concluded by a bibliography and a good index

The report, as a whole, is well done and excellently illustrated by 13 plates and 14 text-figures While it is confessedly superficial, it should be remembered that the economic development of Florida at the present time would hardly warrant the investment of the large sum of money necessary for an exhaustive study of its peat deposits From the commercial view point the present report is surely ample enough to point the way to a utilization of the more important peat deposits and those which are favorably situated for exploitation

Dr Harper approaches the subject from the view point of the plant geographer, and it is this aspect of the report which has the most scientific merit and which will occasion the widest interest A more intensive study and a much fuller treatment of the flora would have been desirable from the standpoint of the botanist, but for the reasons mentioned above such a study was not practicable

The report is weak in its discussion of fossil peat, only two or three occurrences being briefly mentioned. It is very probable, however, that there are no deposits of this sort in the state which are not too small or too deeply buried to be of commercial value. At the same time, the reviewer's experience in the southern states shows that Pleistocene or older peats are more wide-spread, if not more extensive individually, than recent peats, and their botanical records are often of the greatest value. For example such a deposit just across Perdido Bay from Florida contains not only ancestral forms of *Nyssa*, *Hicoria* and live-oaks, but abundant remains of the genus *Trapa*, which is unknown in the existing flora of the western hemisphere.

JOHNS HOPKINS UNIVERSITY

NOTES ON ENTOMOLOGY

AMONG the recent parts of the "Catalogus Coleopterorum" are part 19—Staphylinidæ (1), by A. Bernhauer and K. Schubert, part 20—Aphodiinæ, by A. Schmidt, 21—Gyrinidæ, by K. Alwarth, 22—Tenebrionidæ (2), by H. Gebien, 23—Cleridæ, by S. Schenkling, 24—Histeridæ, by H. Bickhardt, 25—Cebrionidæ, by K. W. von Dalla Torre, and 26—Scraptiidæ and Pedilidæ, by M. Pic.

A NEW French entomological journal is *Insecta, Revue Illustrée d'Entomologie*, published by the entomological station of the faculty of sciences of Rennes, F. Guitel, editor. It is a monthly, and the first number contains articles on orthoptera, coleoptera and economic entomology, all the systematic articles are illustrated.

THE peculiar larval cases of the Cryptocephalidæ and the remarkable larvæ of the Cassidæ with their highly modified tails have always been entertaining subjects with coleopterists. Mr. Karl Fiebrig has added greatly to this interest by his article on these insects.[1] The life history of a number of South American species is given more or less completely, and the plates (partly colored) illustrate many details of structure.

MR. A. M. LEA is the author of an interesting article on the beetles occurring in ants' nests in Australia and Tasmania.[2] Although the paper is a systematic one, there are notes on the habits and occurrence of many of the species. Most of the species belong to the Pselaphidæ, many are new, there are 23 species of *Articerus* and 14 of the curious long-legged Histerid—*Chlamydopsis*. A new family is based on a new genus, *Trelothorax*, placed between the Rhysodidæ and Cucujidæ, the mouth-parts are entirely concealed by the broad mentum, the hind tarsi four-jointed, the others five-jointed, it is a slender insect, with short and broad antennæ.

THE first part of the work on the aquatic flies of Germany is issued, the author being Dr. K. Grunberg.[3] This part includes all the diptera with aquatic larvæ except the Chironomidæ, which will be treated in the second part. There are synoptic tables to the genera and species and in many cases to the genera of the larvæ as far as known. Since many of the genera and a number of the species also occur in the United States, the book will be of considerable use to Americans. The arrangement of the Culicidæ is that generally followed a few years ago.

THE twenty-fourth lieferung of "Das Tierreich" is on the hymenopterous gall-flies (Cynipidæ), and is by Dr. K. W. von Dalla Torre and Professor J. J. Kieffer, 891 pages, 420 figs. About 1,200 species are treated, the genera are used in a broad sense, many recent segregates being sunk as synonyms, or subgenera. Tables are given for the galls of the old and new world. In the back is a list of genera, with references, derivation and originally included species.

[1] "Cassiden und Cryptocephaliden Paraguays, ihre Entwicklungsstadien und Schutzvorrichtungen," *Zool. Jahrb. Supp.*, 12, heft 2, pp. 161–264, 5 pls., 1910.

[2] "Australian and Tasmanian Coleoptera Inhabiting or Resorting to the Nests of Ants, Bees and Termites," *Proc. Roy. Soc. Victoria*, XXIII., pp. 116–230, 3 pls., 1910.

[3] "Die Susswasserfauna Deutschlands," Heft 2A, Diptera, Jena, 1910, pp. 312, 348 figs.

The November-December number of the Hungarian entomological journal—*Rovartani Lapok*—is a jubilee number in honor of Alex Mocsary, for his forty years' service in the Hungarian National Museum Most useful is a list of his numerous publications A list of species (65 in all) that have been named in his honor is given, to which various friends add new species in all orders in this number of the journal

Mr C C Ghosh has published an account of the life-history of a neuropterid fly—*Croce filipennis*[4] These delicate insects are but little known, and a figure of Savigny had long done duty as the only known larva of the family The larva of *Croce* is very similar to that of Savigny, with a large *Chrysopa*-like head and jaws and an extremely slender prothorax, the abdomen broad and flat They live in houses in India, and feed on silver-fish and bed-bugs The pupa is formed within a spherical cocoon, the larval stages last for nearly a year, and the adult appears for only a few days in April

Dr E Mjoberg is the author of a long article on morphology and classification of the biting and sucking lice[5] A number of species are described as new, mostly from the old world, and several new genera One, *Neohæmatopinus*, is made for *Hæmatopinus sciuropteri* Osborn He concludes that both Anoplura and Mallophaga should be included with the Psocidæ in the Corrodentia, as three subequal groups, the Anoplura more closely related to the Mallophaga than either to the Psocidæ A useful bibliography is appended.

Carl Henrich has published a large paper on German plant-lice which will be of use to our students of these insects[6] He divides the family into the usual six tribes, but appears to be unfamiliar with some of the recent generic changes

Dr N J Kusnezov brings up cases of probable viviparity in certain pierid butterflies of northern Russia[7] In examining the anatomy of certain pierids (*Colias*) he found fully developed larvæ in the lower part of the oviduct, and no chlorion around them These larvæ were bent double, with the head toward the aperture He therefore concludes that at least sometimes the larvæ are born alive, or at least so far advanced that the eggs hatch very soon after deposition The reason for this intrauterine development of the embryo he believes is the short season in the northern localities Two species of Tineids have been recorded as viviparous

Nathan Banks

SPECIAL ARTICLES

PROTECTIVE ENZYMES[1]

In this preliminary paper the authors will bring together the results which thus far show some important relations and reactions carried out by certain protective enzymes of fruits This work originated in the efforts of one of us (Cook) to determine the toxicity of tannin It is well known that tannin is one of the most abundant of plant products, and it has been repeatedly stated that it occurs in green fruits Although the work referred to above gave very definite results on the toxicity of tannin, it became evident that there was some factor or factors in the living fruit which had not been taken into consideration, making it necessary to attack the problem from the biochemical standpoint

Pomaceous fruits were most satisfactory for our purpose, although the fruit of the tomato and other plants were also used As the work progressed many difficulties presented themselves, such as the uncertain and more or less unreliable methods for quantitative determination of tannin.

[1] By permission of the Delaware Agricultural Experiment Station

Among other things brought to light by these studies was the very great variability in the amount of tannin at different times and under different conditions It is well known that tannin occurs in great abundance in certain tissues of the plant and in injured parts, and these facts led to original studies on the possible function of tannin in plants However, we did not expect to find the great variation in amount of tannin dependent upon the length of time between the removal of the fruit from the tree and the analysis of this same fruit, for it was finally learned that there was a rapid increase in the amount of tannin or like bodies in the normal fruit immediately after removal from the plant, and that the tannin continued to increase in quantity for some time Although the greatest increase was, as previously stated, immediately after removal from the plant

For instance, a sample was taken by dropping the fruit into boiling water immediately after plucking to stop all enzyme action, and the tannin determined at once At the same time another sample of the fruit on the same tree was injured by repeated puncturing of the stem and fruit with a pin and allowed to remain on the tree for 48 hours, when the tannin was determined In the latter case the tannin was about three times as great as in the former Apples which had fallen from the tree were also analyzed for tannin and showed about twice as much as in the case where the enzyme action was stopped if such was the cause of the action However, it was thought that this action should be traced even further than shown in the above preliminary experiments and the first and best method that suggested itself (Thompson) was to follow the action by tracing the soluble nitrogen in content which would decrease if tannin or a tannin-like body was formed which would unite with the proteid bodies in the fruit juices Accordingly, juices were prepared from a number of different fruits and substances where such action might occur The materials used were green walnut hulls, ripe apples, green apples and pears; they were first ground through an ordinary meat chopper and pressed through canton flannel These juices were sampled immediately after pressing out and every 24 hours thereafter, until fermentation was apparent, the samples being filtered through asbestos by suction, and the soluble nitrogen determined with the following results [8]

Ripe apples—no decrease
Green apples—64 per cent decrease in 48 hours
Pears—14 per cent decrease in 48 hours
Walnut hulls—16 per cent decrease in 94 hours

To further prove that the action might be due to enzyme action one sample of the above walnut juice was brought to boiling temperature and kept there 30 minutes In this case for the first 48 hours there was practically no decrease in the soluble nitrogen, but after 94 hours it showed about 6 per cent

In these experiments it will be noted that there was positive proof of the formation of a tannin-like body that had the power of precipitating proteid matter, thus causing part of the nitrogen to be precipitated in the insoluble form, but as yet the nature of the enzyme was not determined further than this property, although it had been previously shown that the juices had the power of decomposing hydrogen peroxide

Therefore, a similar series of experiments were carried out by grinding the fruit with calcium carbonate, as suggested by Appleman's work on catalase, in which he showed that the activity of the catalase could be preserved by such treatment However, when the juices were filtered off and the soluble nitrogen determined, there was no decrease in any case, but fermentation set up in about 36 hours, which was a considerably shorter time than in the previous experiments.

On allowing the calcium carbonate precipitate to settle and testing both the precipitate and the supernatant liquid with H_2O_2 by the method given by Appleman, it was shown that all of the catalase was carried down by the

[8] Complete data in "The Preparation and Properties of an Oxidase Occurring in Fruits," by H P Bassett and Firman Thompson, *Journ. Amer Chem Soc*, 33. 416–423, 1911.

calcium carbonate and none whatever remained in the supernatant liquid. Accordingly, this precipitate was filtered off on a Buchner funnel and allowed to dry over sulphuric acid.

It is well known that tannin as such can not exist to any considerable extent in the presence of proteid matter, since these two substances form a precipitate, but as it has been shown repeatedly by the ferric chloride and similar tests that a body existed in the plant cells which gave these tests, the conclusion was drawn that this body must be poly-atomic-phenol that would not precipitate proteid matter. Accordingly, gallic acid was selected for our following experiments.

Therefore, a quintuple set of experiments were then carried on, one set with tannin, a second set with gallic acid, a third set with gallic acid plus enzyme, a fourth set with sodium gallate, and a fifth set with sodium gallate plus enzyme. The experiments were made by putting about 33 c.c. of liquid medium in each of a number of 200 c.c. Erlenmeyer flasks. The tannin, gallic acid and sodium gallate were added to the medium in the following proportions: .025, .05, .1, .2, .4, .6, .8 and 1 per cent. The amount of enzyme was constant throughout the two series in which it was used.

These experiments showed that the organism (*Cunninghamella echinulata*) used made its best growth in the check and in the gallic acid, and the next best growth in the sodium gallate. The gallic acid plus the enzyme, the sodium gallate plus the enzyme, and the tannic acid all showed a tendency to check the growth in the lower percentages and to completely inhibit it in the higher percentages. However, the results with the next organism (*Glomerella rufomaculans*) were radically different and led to further investigations. In preparing the enzyme with calcium carbonate, as suggested by Appleman's work on catalase, it has been shown above that the precipitated calcium carbonate carried down the catalase completely, but upon testing the supernatant liquid with guiacum it was shown that the presence of an oxidizing enzyme still existed in solution. However, upon testing the precipitate with guiacum after dissolving out the calcium carbonate and acidifying, with acetic acid, it also showed that a considerable portion of this oxidizing enzyme was carried down by the calcium carbonate, and upon drying this precipitate it was shown to absolutely lose its activity. Thus in drying the catalase precipitated by calcium carbonate the portion of the oxidizing enzyme carried down with it was killed, thus explaining the marked difference, as shown above. It should be stated here that in the first experiment referred to above the calcium carbonate precipitate was not completely dry, while in the second it was quite dry. Thus in the first case a considerable amount of the oxidizing enzyme still existed and exerted its influence on the transformation of the gallic acid into the tannin-like body, while in the second case the oxidizing enzyme had been destroyed by the drying and no such action took place to any considerable extent.

It was now evident that we had two enzymes instead of one, and that they could be completely separated from each other by their properties, as stated above, but in such a large proportion of the oxidizing enzyme carried down by the calcium carbonate precipitate it became evident that methods would have to be devised for obtaining the oxidizing enzyme from the supernatant liquid. Accordingly, the supernatant liquid was drawn off and treated by the general method for enzyme precipitation, namely precipitation with alcohol (60 per cent.). This precipitate carried practically all the enzyme down with it. This was allowed to settle and finally collected on a Buchner funnel. As it had been shown that it could not be dried, it was now prepared for use by suspension in water, and in this manner used in the following experiments. The ferric chloride and other tests on the plant cell contents showed the presence of a poly-atomic phenol, and it was evident that the formation of the tannin-like body from the poly-atomic-phenol could probably be carried out in artificial solutions. However, it has been previously shown by Bertrand in work-

ing with laccase prepared from the sap of the lac-tree, and Lindet with an oxidase found in cider and wines, that these enzymes possess the property of oxidizing certain poly-atomic-phenols, e. g., hydroquinone to quinone and pyrogallol to purpurogallic. Thus the following experiments were planned to study this property of the enzyme by preparing artificial solutions of gallic acid and albumen and measuring the rate and extent of the formation of the tannin like bodies by the decrease of the soluble nitrogen.

Accordingly 500 c.c. quantities of the following solution were prepared:

No. 1—gallic acid alone, 4 per cent
No. 2—gallic acid and enzyme
No. 3—gallic acid and enzyme
No. 4—gallic acid, albumen and enzyme
No. 5—gallic acid, enzyme and albumen
No. 6—enzyme alone

The albumen used was a solution of egg white which had been filtered through absorbent cotton and contained 1.36 grams of nitrogen per liter. The enzyme was prepared from pear juice by grinding fruit in calcium carbonate, pressing out the juice and allowing it to settle, drawing off the supernatant liquid and precipitating the enzyme with 60 per cent alcohol, collecting on Buchner funnel, and suspending this precipitate in distilled water. Fifty cubic centimeters of this suspension was used in each case. A series of experiments similar in every particular except 50 c.c. of 3 per cent hydrogen peroxide was added in each case, and was carried out in the same time. In about an hour after the enzyme had been added a very heavy flocculent precipitate had formed and settled, in those flasks containing all three constituents, viz., gallic acid, albumen and enzyme. Those containing gallic acid and enzyme without albumen had turned a rich wine red color, presumably from the oxidization of the gallic acid.

Samples of 50 c.c. each were taken after 15 hours, and every 24 hours thereafter until there was no longer any decrease in the nitrogen or until the solution showed signs of fermentation.

No. 2 containing gallic acid and albumen, showed no change in soluble nitrogen after 5 days.

No. 4, containing gallic acid, albumen and enzyme, showed a marked decrease in soluble nitrogen amounting to 70 per cent in five and one half days, 26 per cent being precipitate in the first 15 hours.

The corresponding solution containing hydrogen peroxide showed a similar decrease, but was considerably more rapid, amounting to 47 per cent in the first 15 hours.

Having made this further investigation, as outlined above, thus determining some of the properties of this oxidizing enzyme and at the same time explaining our former results, it was now desirable to try the effects of this pure enzyme preparation upon certain fungi. Therefore *Cunninghamella echinulata*, *Glomerella rufomaculans*, *Pestalozzia brevisela* and *Penicillium aureum* were used in a quintuple set of experiments according to the method previously referred to, but using the pure oxidase instead of the calcium carbonate precipitate. In all cases there was decided action increasing with the increased amount of gallic acid or sodium gallate used.

Since the above experiment showed such high toxic effects which could not all be accounted for by the fermentation of the tannin-like body, it was decided to carry out further experiments on the germicidal properties of the solutions formed. It had also been previously noted that the juices that had been prepared by grinding with calcium carbonate, and in which there was apparently no action of the enzymes fermented much more readily than the juices that had been prepared by grinding without calcium carbonate, and it was evident that the other bodies formed in the reaction might have some germicidal properties. Accordingly, six days after the experiment with gallic acid to show that the precipitate of the soluble nitrogen had been started, plate cultures on agar-agar and gelatine were made from the solution containing gallic acid and albumen, gallic acid, enzyme and albumen, enzyme and albumen. Cultures in beef tea were also made at the same time

Ninety-six hours after the setting of the cultures the following results were noted. In both cases where the gallic acid and enzyme were not present together there was a heavy fungus growth, but in both cases where they were present together there was a very slight growth in all media. Thus the conclusion would be that the body formed by the action of the enzyme and gallic acid had a marked inhibitive effect on fungus and bacterial growth. It was apparent that for these germicidal effects to be of any value to the fruit it would necessarily have to have quite a rapid reaction in order to keep out any chance of infection, and also from the almost instantaneous appearance of the precipitate, and from the data obtained for the transformation of the soluble nitrogen it was inferred that the action was comparatively rapid, and accordingly an experiment was planned to obtain further data on this point. A solution consisting of 100 c.c. of albumen solution, 200 c.c. of 1 per cent. gallic-acid solution, 50 c.c. of enzyme suspension, and 50 c.c. of 3 per cent. hydrogen peroxide was prepared and diluted to 500 c.c. Another solution which was the same in every respect with the exception of the hydrogen peroxide, which was omitted, was prepared at the same time. Samples of these two solutions were taken every fifteen minutes, for about two hours, and the soluble nitrogen determined. The solution could not be obtained clear on filtering and no flocculent precipitate separated out as in the previous cases. The determinations of nitrogen also showed no decrease in the soluble nitrogen. Thus it was apparent that for some reason the action was not taking place as before, but on adding 60 c.c. more of the enzyme suspension in each case, a heavy flocculent precipitate immediately formed and settled rapidly, and the first sample was taken ten minutes later, filtered as rapidly as possible, and the soluble nitrogen determined showed a decrease of 42 per cent. in the solution containing the hydrogen peroxide and 53 per cent. in the other.

The same experiment was then repeated with the constituents in the same proportions, but the quantity of the enzyme suspension was increased to 150 c.c. The flocculent precipitate appeared at once and settled immediately. Samples were taken every 15 minutes for the first hour, and at longer intervals thereafter for 4½ hours. The decrease in the soluble nitrogen amounted to about 30 per cent. in the first 15 minutes in the solution containing the hydrogen peroxide, and about 23 per cent. in the other. There was, however, practically no further change in the soluble nitrogen, up to four and one half hours, when the sampling was discontinued.

These results no doubt show conclusively that the action carried out by the enzyme is very rapid, but will take place only when the concentration is above a certain undetermined minimum, which point is of very great importance when acting as a protective agent for the fruit.

Analysis of the fruits (apples and pears) made throughout the season, where identical conditions were adhered to, showed a gradual decrease in tannin content. It is well known that fungus parasites increase in activity throughout the season and are most destructive as the fruits approach maturity. Later in the season tests were made for the determination of the localization of the enzyme in the fruit by the use of the guiacum solution, which showed that in the case of pears the blue color developed first around the core and immediately under the peel, but finally developed uniformly over the freshly cut surface. As cold weather approached, the pears were removed from the trees and stored in a cool, dry place, by which means it was hoped that the work might be continued for some time. An attempt to prepare some of the enzyme from these pears eight days after their removal from the tree resulted in a preparation which had lost practically all its power. On testing the freshly cut surface with guiacum solution no blue color was developed, excepting rather faintly immediately around the core. The supply of pears having been exhausted, apples were examined in the same manner from time to time, and showed a gradual decrease in the amount of enzyme

until to date (February 8 1911), showing only a slight trace around the inner part of the core

It is interesting to note that early in the season several normal fruits were injured by passing a sharp instrument through them from side to side and allowing them to remain on the tree for 48 hours thereafter A section was then made through the injury and the guiacum solution applied The blue color developed first quite strongly around the walls of the injury, followed gradually by the other parts of the pear

From the preceding it will be readily seen that there exists in the normal living fruit two enzymes, a catalase and an oxidase The latter is probably most abundant in the early part of the season, gradually decreasing in activity as the fruit approaches maturity and ripens Furthermore, from the above results it appears that tannin as such does not exist in any part of the normal, uninjured fruit previous to maturity, except possibly a small amount in the peel, but exists as a poly-atomic phenol, which upon injury is acted upon by the oxidase and forms a tannin or tannin-like body having the property of precipitating proteid matter, and at the same time forming a germicidal fluid This oxidase acts only in an acid solution, and when present in an amount above a certain undetermined minimum The above conditions are always present in normal immature pomaceous fruits When normal, immature fruits are subjected to injury by fungi, insects, or mechanical agencies, the action of the oxidase on poly-atomic-phenol is brought about with the effects as stated above

THE RELATION OF PERMEABILITY CHANGE TO CLEAVAGE, IN THE FROG'S EGG

UNFERTILIZED eggs (taken from the uterus) of the wood frog, *Rana sylvatica*, were caused to assume the normal orientation in the jelly, and to segment, by electrical stimulation An alternating current of 60 cycles and 110 volts was passed through the tap water containing the eggs, from platinum electrodes about two inches apart Stimulation for one second seemed to give the best results The eggs were placed in fresh water immediately after stimulation

Similar eggs were caused to segment by mechanical stimulation, even while the jelly remained intact However, the most reliable mechanical means of inducing cleavage was found to be Bataillon's method of pricking the egg with an extremely fine needle The first cleavage furrow often passed through the point of puncture

Thousands of eggs were operated on Control eggs were kept to both sets of experiments, and showed no segmentation or rotation within the jelly

The following indirect evidence is given to show that a change in permeability is associated with both of these means of inducing cleavage

1 These "stimuli," if applied in greater intensity or duration than is necessary to produce cleavage, result in rapid osmotic exchange with the medium and death of the egg

2 Similar electrical and mechanical "stimuli" produce segmentation in the sea-urchin's egg, a process which I have shown to be preceded by an increase in permeability

With the exception of the rate of oxidation, this change in permeability is the only known common intermediate step between fertilization or artificial "stimulation," on the one hand, and cleavage on the other Furthermore, there is indirect evidence to show that increase in permeability is associated with fertilization, in the frog's egg, as I have shown to be the case in the sea-urchin's egg Backman and Runnstrom[1] observed that, whereas the osmotic pressure (freezing point lowering) of the ripe ovarian egg of the frog is the same as that of frog's serum, the osmotic pressure of the fertilized egg is the same as that of the pond water in which it lies Since the frog's

[1] *Biochem Zeitschr*, 1909, XXII, 390

egg does not swell enormously after oviposition, it is improbable that the fall in osmotic pressure is due to the absorption of water The simplest explanation is that the egg is, at this time, permeable to the internal osmotic substances That this permeability is only a temporary condition is indicated by the fact that the osmotic pressure of the resulting embryo rises until it reaches that of frog's serum

In conclusion, I wish to thank the Carnegie Institution, and especially Dr Chas B Davenport, the director of the laboratory

THE BACTERIOLOGY OF "TATTÉ MELK"

This milk is a favorite food article in Norway and Sweden and is prepared by inoculating sweet cow's milk with leaves of *Pinguicula vulgaris* or with a small amount of the finished product Sometimes pieces of linen are dipped into the fermented milk, allowed to dry, and used for inoculation This method makes it feasible to send the material by mail The milk is thick and slightly stringy and has a slight cheesy taste and odor

I obtained three samples of the milk and one of the impregnated linen from a reliable source for the purpose of determining the active agents in it A microscopic examination of the samples showed streptococci in large numbers, mostly in diplococcus form, but frequently in chains of ten to sixteen members Two species of yeasts were also in abundance, one being an oval yeast, the other a large organism with square ends, often forming long filaments Besides these organisms there were present some bacilli resembling *B coli* in shape and size, which proved to be gram-negative There were also a few large bacilli resembling that group of bacilli, which is found in milk almost invariably and forms larger amounts of acid than ordinary lactic acid bacteria Microscopic examination of the impregnated linen did not show yeast cells

Plates were prepared from the four samples in dextrose-litmus-agar and in beerwort agar, litmus milk was inoculated with the original material The milk, when intended for consumption, is inoculated at body temperature, and therefore all plates and cultures were incubated at 37° C

There was no difficulty in isolating the different organisms from the plates The streptococcus could not be distinguished microscopically from *S lacticus*, but its action on sterile milk differed in that it coagulated but slowly, after coagulation the coagulum was stringy, similar to the coagulum formed by *B bulgaricus*, but in a smaller degree The oval yeast gave the microscopic picture of *Saccharomyces cerevisiae* It ferments lactose and saccharose with violent gas production, levulose slowly, and maltose not at all Cultures of this yeast in liquid beerwort impart a somewhat stringy consistency to the medium The other yeast proved to be *Oidium lactis*, which is always present in milk and in this milk is probably responsible for a slight cheesy taste and odor

Cultures of the samples were also made in broth with the addition of 2 per cent dextrose and 0 5 per cent acetic acid The presence of the acid restrains most bacteria, so that those forming a large amount of acid can be detected by this method Dextrose also favors the growth of these bacilli After twenty-four hours' incubation they were found in abundance in the cultures These organisms, however, do not multiply readily in milk in competition with other bacteria and I do not believe that they have any bearing upon the production of "Tattó Melk" In fact sterilized milk, inoculated with streptococci, isolated from the samples, and with the two species of yeasts, resembled the original product closely after twenty-four hours Whether the yeast has anything to do with the stringiness of the milk is doubtful, but it adds to the palatability of the milk It does not produce nearly as much gas in the milk as it does in pure culture

University of Chicago

PERMIAN REPTILES

THE relationships of the South African and American Permian faunas have long been of profound interest, from both the geological and evolutionary standpoints. Students have now generally come to an agreement in the union of all the Permian and Triassic stegocrotaphic reptiles (exclusive of the Chelonia) under the single order Cotylosauria, but, until recently, the zygocrotaphic terrestrial reptiles have been distinguished under five or six ordinal names, though Broom is willing to unite the African forms under the ordinal or superordinal term Therapsida.

Within the past few years, beginning with the important collections made by Professor Case, the University of Chicago has acquired a very rich representation of the American Permian reptiles and amphibians, some six or seven of the thirty odd genera acquired represented by practically complete skeletons. Among the latest of these collections, discovered the past year by Mr. Paul Miller in the vicinity of Seymour, Texas, is a very nearly complete articulated skeleton of the remarkable genus described a few years ago as *Seymouria* by Broili, from two incomplete skulls. Almost nothing of the remainder of the skeleton has hitherto been known. Within the past year I described and figured a considerable part of a skeleton of a very small reptile, based upon two specimens of nearly identical size, under the name *Desmospondylus*, suggesting at the time the possible identity with either *Seymouria* or *Pantylus*. The name proves to be a synonym of *Seymouria*. Although the two specimens described are scarcely a third of the size of the adult, and both of the same size, they doubtless are juvenile, or embryonic. I also suspect that *Conodectes* Cope is the same genus, or at least is a closely allied genus, but the name is unworthy of priority, since the type was never really described or figured.

Seymouria presents such extraordinary characters, that, if we raise the Diadectidæ, Pariotichidæ and Pantylidæ to subordinal rank, as would be justified from the characters used to distinguish the South African groups, we must also elevate the Seymouriidæ to the same rank. I am, however, opposed to the erection of so many ordinal names, they are in large part merely confessions of ignorance. The family Limnoscelidæ, for instance, recently described by me from the Permian of New Mexico, shows certain intermediate characters between the Diadectidæ and Pareiasauridæ. For the present, it seems to me that the following classification will suffice: Order Cotylosauria, families Diadectidæ (Nothodontidæ Marsh), Limnoscelidæ, Pariotichidæ, Seymouriidæ, Pantylidæ, Pareiasauridæ and Procolophonidæ, the last two exclusively African and European, the others exclusively American.

And I would go still further, possibly some will think too far. The possession of a very perfect skull of *Edaphosaurus*, hitherto known from imperfect material only, convinces me that Broom is right in his acceptance of the views previously held by Cope, but which for some years have fallen into desuetude, that the African and the American therocrotaphic reptiles (that is, those with a lower temporal vacuity only) are likewise related in the same way and perhaps in the same degree. Broom would still retain their ordinal distinction, but I am disposed to go further and reunite them under the name originally applied by Cope to the Pelycosauria and Anomodontia—Theromera or Theromorpha. The working out of the genus *Casea*, recently described by me, has disclosed many aberrant characters, separating the genus more widely from the Pelycosauria than are any two groups of Broom's Therapsida. But, I repeat, I am not willing to make so many new orders, it serves no useful purpose, and both *Edaphosaurus* and *Casea* would require ordinal distinction if we accept the groups of Therapsida as orders. I therefore propose the following classification of the therocrotaphic reptiles (excluding the Theriodontia): order Theromera, suborders Pelycosauria, Poliosauridæ, Edaphosauridæ, Caseidæ, Aræoscelidæ (?), Therocephalia, Anomodontia, Dinocephalia and Dromasauria, the first five American, the others African. I leave the

family termination to some—one can do what he chooses with them S W WILLISTON

SOCIETIES AND ACADEMIES

THE PHILOSOPHICAL SOCIETY OF WASHINGTON

THE 691st (40th anniversary) meeting was held on March 11, 1911, President Day in the chair The evening was devoted to hearing the annual address of the retiring president, Mr R S Woodward, who spoke of the "Meaning of Research"

The speaker mentioned the importance of the time element in measuring progress in research, and stated that we are often prone to measure progress by months and years instead of decades As a study of the society may throw some light on the meaning of research, the speaker briefly reviewed the great work the Philosophical Society, which is yet young, has done, what it is for and what it may do

The society has had thirty two presidents, of whom the speaker had known all except two, and he had worked with two thirds of them The chief work of many of these were mentioned Forty years ago was a time of profound intellectual agitation, the principal cause of which was Darwin's "Origin of Species," and it is probable that the Philosophical Society was due to the great influx of new ideas coming at that time Stirring intellectual enterprise (not repose) was the order of the day At that time biology was the most conspicuous sign of the intellectual uprising, the work of Kelvin and Tait, and Maxwell was not more revolutionary than Darwin's Progress has since been at an accelerated rate Applications of results of physical science have multiplied ten to one hundred fold

The development of scientific work by the government was described at some length, mention being made of a number of departments and individuals therein that have contributed to both practical and theoretical results in many branches of science, including medicine, most of which had been done by members of the Philosophical Society The characteristic features of research by members of the society during these years were mentioned

Research has not been understood by the masses, and has not generally been recognized as a vocation The methods of science are now coming to be recognized by all as the best method for the discovery of truth The meaning of research is best recognized by the fruits of this and other similar societies

The chair expressed the thanks of the society to the speaker for his excellent address The address will soon appear in full in a bulletin of the society

THE 692d meeting of the society was held in the new auditorium of the National Museum on March 25, 1911, this being a joint meeting with the Washington Academy of Sciences The evening was devoted to hearing an address by Dr Svante Arrhenius, by invitation, on the subject of "The Atmosphere of the Planets"

The constitution of the sun and its probable temperature were briefly mentioned Owing to its gaseous condition the specific gravity of the sun is about one fourth that of the earth, that of Jupiter and Saturn being about the same as that of the sun The majority of the planets are void of an atmospheric envelope The moon's atmosphere is about one thousandth that of the earth

The critical velocities of bodies at the earth and at the moon were mentioned In speaking of the critical velocities of various substances at the moon it was stated that hydrogen and helium had long ago flown off from the moon

The minor planets, lying in orbits between the sun and Mars, have no atmosphere Mars, Venus and the earth only, have an atmosphere Venus has a very heavy atmosphere and which is now like that of the earth ages ago

Laplace's theory of the extension of the sun's gases to Neptune and Uranus was mentioned

The question of how the earth got its present atmospheric properties was discussed When the temperature of the earth reached 55° C organisms could live The polar regions of Venus are about 60° C and organisms may live there

In discussing the important function of the existence of CO_2 in the atmosphere, it was stated that the time will come when the amount of it will dangerously decrease, and finally all of it and some of the water will go from the earth, the earth will grow colder and the rest of the water will freeze

Mars is now a desert with a low temperature, its atmosphere is about one twentieth that of the earth This will nearly all vanish, especially when the sun's radiation allows Mars to cool down This is the fate of all planets

President Day, of the Philosophical Society, thanked the speaker, on behalf of the joint meeting, for his very interesting address

BOTANICAL TEACHING[1]

I ON THE PREPARATION OF BOTANICAL TEACHERS

SOME months ago a suggestion was made that at this dinner we should ask ourselves the question Why is it that with the enormous classes we are having in botany there is a marked dearth of properly trained men who can serve as instructors in colleges and universities?

In order to be sure that I was right in regard to such a dearth I wrote to something like a dozen of the professors of botany in prominent institutions in the country, making the inquiry whether they had noticed the same thing, and uniformly the answer was that there seems to be a shortage in the supply of material for instructors (in the college sense) and young men for other minor positions

I think there is no lack of men who are ready to be professors of botany I am very certain that there is no trouble here, but when a professor who knows what he wants asks for a man who can take up this work or that work as an instructor, the situation is quite different

What becomes of the great number of students who are in our classes? The professor of botany in the University of Minnesota tells me that he has over 500 students in his beginning classes In Nebraska we have about 350, and elsewhere I find essentially the same thing Enormous classes are pursuing general botany, and

[1] From the stenographic report of oral addresses delivered at the conference on botanical teaching at the dinner for botanists, Minneapolis, December 29, 1910

yet so few are going on and qualifying for even the minor teaching positions.

In talking this matter over recently with a clergyman, who is also a botanist, he said, "The truth is there is less real scholarship among students to-day than there used to be," and I think there is a grain of truth in his remark.

I stopped our professor of Greek the the other day and asked him what he thought of our botanical problem. He said, "It is just because the students have got into the way of taking nothing but first-year work. They take first-year Greek, and that is the end of it, first-year college Latin, first-year geology, first-year philosophy, first-year physics, first-year astronomy, and first year American history, and so on." There is a good deal of truth here too.

Here then is something to be thought of. Students in the universities are taking beginning work only, and botany suffers with all other subjects. As educators we should give serious consideration to this matter. It is not right that we should permit pupils to be taking these little educational bites of all kinds, and in any sequence; on the contrary they should be required to sit down to a good square educational meal taken in proper order.

It makes one sick at heart to witness what is actually going on in the universities under our very eyes. We spread out before the students the courses we have to offer, and in tempting phrase try to induce as many as possible to enter our classes. I am reminded of the proprietors of bazars who have trinkets for sale, and try to induce every passer-by to purchase, by loud insistence upon the advantages resulting from such a transaction. And the bewildered student is left without a guiding suggestion in the bulky catalogue. Oh, the folly and the cupidity and the cowardice of the system that bids the student make a wise choice, but gives him no guide! Had I the power I should certainly sweep out of existence all of the go-as-you-please arrangements in the universities, and I should substitute for them a logical and carefully selected sequence of studies.

There is no doubt that many young men turn from botany into various related subjects, as agronomy, horticulture, forestry, etc., and I have no complaint to make if they do, but these subjects do draw students away from scientific botany, and so reduce the number available for teachers.

Nearly every one of the professors to whom I sent inquiries referred to the low remuneration that comes to the young man who has fitted himself to be an instructor in botany in college or university. And no doubt this is a potent factor, and it is likely to turn away many of the best men from the teachers' ranks. The fact is that a bright young man looking to his life-work will be turned more or less this way or that way, as he sees that the world is ready to pay him for it. Now I dislike to have to say this; we like to think that the best men will go forward if they have to go with only a crust a day, and all that. There is very little truth in it, however. We ourselves go where we find employment and adequate remuneration. And so young men are lured away from botany with its low remuneration, leaving us too frequently only the poorer men.

Now we do not like to acknowledge this condition of things. We like to think that science is a sacred calling, something apart from business, and we do not like to acknowledge that a man who has the scientific spirit in him can possibly be turned aside by any thing like a salary. But botany is a business, and it is not sacred any more than selling shoes or editing a newspaper is sacred. And as most men

can succeed in more than one of several pursuits, so most men can succeed in botany if they take hold of it seriously Here again we do not like to acknowledge the truth of this statement, we think that we are made of different kind of stuff But I do not believe it for a moment I have no doubt that some of us here might have been millionaires if we had gone into business What I want to insist upon is this that we look at this matter squarely, and not try to make out that we are a different kind of people, and made out of different material We are not, and our business isn't any different, it isn't any more sacred We must be candid in this matter and admit that our profession hasn't anything sacred in it, there is no sacred fire that must touch every man before he can be a botanist There is nothing in this sentiment As I said before, botany is comparable to the selling of shoes, or the running of a newspaper Botany is not extraordinarily difficult, and it does not require geniuses, only just good ability and perseverance, that's all So men who might have been botanists will continue to choose other vocations, and some others will choose to become botanists, and some of either will fail, and some will succeed, just as is always the case Some men who might have become brilliant botanists will become brilliant business men instead It has been said that "botanists are born and not made" Maybe they are, but if so, they are born with a multiplicity of other possibilities also

Brethren, let us remember that we are quite like other men, and that with us the factor of remuneration cuts as great a figure as it does elsewhere in society, in the selection of a vocation

Many of those to whom I wrote expressed doubts as to the wisdom and effectiveness of some of our teaching, and out of these doubts that have been passed along to me I obtain these suggestions

There is some faulty elementary instruction, probably I should have said much faulty instruction Again, we do not begin early enough in bending the human twig in the right direction to make a good botanist There is a good deal of improper presentation We too often try to offer "attractive" courses for the sake of drawing students into our work And this is necessarily fatal to a scientific presentation Some of my correspondents suggest that there are such persons as incompetent assistants who supervise our laboratories, and by their incompetence tend to drive away some men Further, it has been suggested that probably there is nowadays too great a neglect of field work It used to be that in vacation time the young botanist had something to think about, and something to do He could go out in the woods on long botanical trips He can not do this to-day if he is a mere laboratory man He can not conveniently carry his microscope along with him A vasculum is a great deal easier to carry than is a microscope, and far easier to handle I think my correspondent was right we have lost something of our hold on young men because we have nothing to substitute for the old-time field botany You can not do laboratory work in vacation Of course you can go to summer school, and sit down by the side of a lake and study some of the algæ found there, but even that doesn't compare favorably with the old-time tramping for miles and miles through the woods and swamps, with a vasculum slung over your shoulder

Some of my correspondents suggested that there is too much narrow training nowadays I think this probably comes rather close to some of us We get hold of a bright young fellow after he has had a half year's work, or little more, and put him

into something that narrows him to a single line of work. He makes a good specialist, but he is too narrow for a botanist. He is far too narrow a man to be put in charge of classes in general botany.

Again, I think we set our requirements too high for the young teacher. We demand much more than is really necessary. We older men forget how very little we knew when we began teaching. We act as though we felt that men must be stuffed with every detail of technical knowledge before they are ready to be sent out as teachers. We want these men to be prepared all around, and well prepared, too. This is all right enough when you are thinking of specialists to fill positions calling for a particular preparation. But when the inquiry is made for a young man to be an instructor we should go back to our own experience. We did not know much, but we got on somehow, and our classes seemed to learn from us. Yet to-day we act as though we felt that we must send out young teachers who are perfect machines for any kind of botanical work. We act as though we were not sending out men with initiative and with ability.

Let me illustrate my meaning by an example. A few years ago the government sent to Nebraska for a young fellow who was not especially well prepared in botany and took him to Washington, and after a few days shipped him down to Alabama, and put him in charge of a group of men. They were studying pecan tree diseases. This man from northern Nebraska, who had never seen a pecan tree, found himself in charge of a squad of men engaged in budding pecans. He knew nothing about budding pecans. But he had initiative enough to master the situation, and after a night's study and practise he went ahead as though he had been budding pecans all his life, *and succeeded!* I did not train that man in pecan budding, in fact I could not have recommended him as a budder of pecans. Yet he "made good," not because he had been stuffed by the right kind of knowledge, but because with his foundation of knowledge he had energy and ability.

Now let us ask whether we are not setting up a wrong standard? We are thinking of how full a man is of the botany we have put into him. Should not our attitude be this: "this man has made a good beginning, he has the right kind of material in him, take him and let him grow up with his work."

Now there is not one of you here who has not learned ten times more of botany out of college than he learned in college. You had the qualities in you to make you successful, and had a fair beginning in the science. I was quite interested in looking over the summaries in the second edition of the "American Men of Science" to find that the botanists are requiring young men to work longer for their bachelor's and doctor's degrees than are the chemists, physicists, zoologists, mathematicians or geologists. I do not believe botany is proportionally that much harder. We are putting too high a value on what we are *putting into* our students, and neglecting the man himself. We are in danger of having men grow "stale," as the athletes say. Probably we keep our men with us too long. We should send them out while they are still fresh and vigorous.

I think we should map out very definitely a series of successive semesters of work that should constitute fair preparation for the average young man who wishes to become a botanist. Such a botanist should be ready to begin teaching, or even investigating, not as an expert, but as a beginner. And every one must necessarily be a beginner in his work at one time in

his life Let us think of these young men that we are suggesting for positions as beginners merely, and when you send one to me I shall take him as a beginner, not as a finished botanist Yet very commonly we say to our students that they can not begin either investigating or teaching until they have made a special study in particular fields We try to impress them with the great importance of graduate work, and the littleness of their present knowledge, and we impress upon them also our conviction of their general inability

We need broad general courses with definite beginnings and endings, and including something of all the phases of the science, well wrought together into one science, and not courses consisting of a collection of disjointed and disconnected phases of the subject I think here is one of our mistakes As one of my correspondents wrote very emphatically, "this splitting up of the science so that the student thinks of it as morphology, so many hours, physiology, so many hours, pathology, so many hours, and mycology, and algology, and bryology, and taxonomy, etc, has done much to discourage young men"

No doubt also we can help to make more botanists by encouraging an *esprit de corps* among our students, whether they are undergraduate or graduate students All are botanists, even the newest recruit belongs to the botanical army Let us not withhold honor from these new additions to our force And yet I have seen in many places a tendency to persistently belittle the knowledge of the student in his first and second years on the theory, I suppose, that it is good for a young fellow to be "taken down," and made to feel that in this stage he is little better than a fool. I do not think this is right.

Another thing that we can do is to study our men, and select the more promising And we must not be too particular, either, in our choice I have seen some rather unpromising men turn out to be very successful botanists We must not turn men away simply because at first they do not seem to be promising Some slow men finally become good botanists and successful teachers On the other hand, I have known some brilliant men who in the end have done very little with all their brilliancy I feel sure that as teachers we should frankly tell our students what we think they are able to do Let us stop looking for Torreys, Grays, Farlows, Barneses, Coulters, etc That, however, is what we are doing We are putting up a standard that is only reached once in a long while Let us realize that the young fellows in our classes are very much as we were—just mediocre men Most of us are that, but we got on somehow,' and have been measurably successful And so will they Give them a chance

Then I fear that we have not treated botany as a profession, but merely as a subject of study Of course it is to be studied, and of course, also, it is to be taught But it is also a profession, and we should weave into our instruction much of the ethics of the science, whether it is to take the form of teaching or investigation The young botanist should be made to feel that he is going to *use* his botanical knowledge, and that he can do so with entire propriety Let us stop saying to the young man "You do not know enough yet to begin"—but let him begin!

Now, before I come to my closing discussion I want to make a slight digression in order to speak of college courses in general, and especially the go-as-you-please method to be found in most of our institutions I fully believe in having work prescribed as to kind and place in the college curriculum I believe in prescribing the

necessary language work early in the course. I believe also in prescribing the other science work. The old-fashioned classical courses, with some modifications admitting science, appear to me to be about the best foundation. You ask me why so? For the reason that they began at some place and ended at some place. There was consistency and continuity, with resultant training. The so-called "free elective" plan is to me the worst of all plans. The student is dazed by the many things that he can do, and he does not know what to do. In most institutions, he is supposed to have an adviser, but, as Abraham Flexner shrewdly says, "the advice is equivalent to perfunctory consent to propositions which the student himself submits." So the student generally ends by doing a lot of the easier things in a hodge-podge, aimless manner.

Now let me make a few suggestions with regard to the courses in botany. I fear that I may shock some of you by some things I am going to say.

In the University of Nebraska we are working on a three-year schedule (in a four-year college course) for undergraduate work in botany, intended to fit men for filling instructorships in botany. I do not believe in the "quick-meal" process in education, but as I look over what I have been doing the last forty or more years, it seems to me that we can concentrate our work to such an extent that a man who brings proper preparation otherwise to the work ought to be able, in three years, if properly guided, to complete the course. We are making this schedule aggregate from twenty to twenty-five hours only—not quite the equivalent of a single study taken three years. In this time we think it is possible to take a bright young man and fit him well to begin work. Of course he will not be the equal of our older men. Let us, however, give up the idea that we can turn out young men who know as much as Dr. Coulter or Dr. Farlow. That will take years, but a man can have a good preparation for teaching botany, as good as the young engineer gets—and he is ready for work when he finishes his course. So we are working on a three-year schedule and I think we are going to accomplish with it what has hitherto taken a much longer time.

We are proceeding with the following limitations. First. Such a three-year schedule must include a general survey of the plant kingdom.

Second. This three-year course must include the essentials of cytology and histology. It may not include an extensive knowledge of them, but their technique at least, and enough so that a man has mastered a few, at least, of the principles.

Third. Such a schedule must include the essentials of plant physiology.

Fourth. It must include also the essentials of taxonomy. I will not attempt to say how much that should be, and yet I am certain that there should be a considerable knowledge of taxonomy in regard to the plants that a man is likely to come in contact with. I should feel embarrassed if called upon to teach in a part of the world where I did not know what the plants around me were. I would not like to employ a man in my department who would frankly confess that he could not tell an ash tree from a maple.

These are some of the things that should be known. There are many things I have not included, but I think that what I have put into my schedule will fairly prepare a young man for beginning to teach. He can not take my classes, perhaps, nor Dr. Coulter's classes, but he can begin where we began in teaching, and *work up!*

Now this amount of botanical knowledge,

as I have mapped it out, is very much more than many of us had when we began It should fit a man for beginning to give instruction in the smaller colleges or in the minor positions in the universities It should fit him to lead intelligently the students that come to him in our normal schools I take it that it is in this direction that we must move if we are to be able to supply from our schools and our universities the men who are to follow us

You will notice that in all this I have said—"men" I have said so because I have found that when the demand comes, it is mostly for men I do not know why this is so We say very pretty things about our women students, and give them good high standings, and say complimentary things about them *as students*, and yet when you yourselves look around for some one to be an instructor, and we write and say—"there is a young woman here who will make a good instructor"—you say "Our present circumstances are such that we can not employ a woman" Here is one thing that we ought to change The supply of competent women is much larger than of competent men, and I can assure you from experience in my own department that they make admirable instructors

I have gone over this problem of the making of botanical teachers in this rapid way in order to stir up thought along many lines For I hold that it is a serious problem, and that we as teachers of botany owe it to the future that we should prepare in a proper way for the succession of teachers that must follow us

CHARLES E BESSEY
UNIVERSITY OF NEBRASKA

II THE PRODUCT OF OUR BOTANICAL TEACHING

NOTWITHSTANDING the frequent assertion that teaching of botany is not what it should be, it seems safe to say that there was never a time when there was more good teaching of the subject than we have to-day That we should have dissatisfaction at a time when so much good teaching is being done, is not at all surprising, inconsistent or undesirable Botany itself has grown so rapidly, its call for new researches has been so insistent, its place in the applied sciences and in the affairs of men in general, has assumed such prominence and importance, its use as a means of giving a proper education in scientific thought about things that are worth knowing has been so vigorously claimed, that in consequence our attention is directed as never before to the possibilities and errors of botanical teaching

The teaching is not poorer—we merely know more about it Present practises are not wholly bad and need not be discontinued, but with the increasing richness and diversity of botanical knowledge, and with better definitions of the purpose of science education, particularly education by means of botanical science, we need to consider our practises anew If a prominent feature of reform is discontinuance of past vices, a feature of progress is discontinuance of past virtues for better and larger ones

If the product of our botanical teaching does not meet our ideals, we should look for explanation to some or all of the factors or causes of the very complex situation which confronts us

1 First, what are our ideals? What do we wish to accomplish through botanical teaching? Do we wish to use the study of botany as a means of developing on the part of the people in general a more dependable method of thinking, better reliance upon native powers of observation, experimentation and interpretation, an attitude that demands evidence before judg-

ment may be given, or do we wish to make knowledge of plant life, its structures, processes, habits and uses, the possession of the people in general in order that they may know more, enjoy more, or may more effectively adapt plant life to their economic uses? Do we wish to prepare students who shall take up research in botany to the end that unsolved problems may have solution? Or have we any definite purpose for botanical education other than that since botany is a field which we have found most interesting we wish to "pass it on" to others?

The ends which we seek certainly should receive the careful attention of all who are engaged in general botanical instruction. Research in botany is not the goal of general botanical education, and botany can not claim a place in the general curriculum of the high school or college if its primary aim is to prepare students for research in botany. On the other hand, research is perhaps the most important by-product of general botanical instruction, since when general courses of instruction are efficient there develop well-grounded students who desire to become investigators in the subject.

The purpose must be more serious than to give passing enjoyment, stimulate curiosity about plants, or to minister, as early botanists sometimes said, to the emotional nature of young ladies. There is great need of development of a rigorous scientific attitude toward plant phenomena. Plants and their products are our constant companions and there are certain fundamental facts and principles that people should know about them. If they learn these facts and principles in a way that develops care in observation, in experiment, and in proper thinking, I believe there is also secured enjoyment of plants and ability to make economic use of them. This central foundation in method and content should be best upon which to build research work. It would seem also that research would find a large number of worthy devotees if general courses of instruction were presented as broadly fundamental to the science, and more significant in practical affairs.

2. A second factor has to do with the quality and preparation of the students who present themselves in our college courses. From an amount of data too limited for final conclusion, it seems that most of the students who elect college courses in botany have had no botany in secondary schools. For some reasons, secondary school courses seldom lead students to take botany in college, or else college requirements prevent their doing so until they have become engrossed with other lines of work. Possibly the difficulty lies in inefficient courses or teaching in secondary schools. These courses have been accused of being too formal, too technical, too closely limited to a special field of botany, not sufficiently full of meaning to young students. Secondary courses in botany have also been accused of being too difficult—an accusation which I think is untrue. It is not, for example, the inherent difficulty of alternation of generations, but lack of any appreciable motive for studying it, which makes it seem difficult. The structure and workings of a steam engine or an automobile are more difficult, but they are "going things"—dynamic—and students solve their mysteries. If an appreciable motive is put into secondary teaching of botany its difficulties are solvable.

Possibly some of the difficulty lies in the fact that the different sciences are incoherent and intermittent in the high schools. In a valuable recent investigation made by an eastern biologist records were collected from 276 high schools. Botany is taught in 225 of them. It is distributed in the

different years of these high schools as follows first year 76, second year 94, third year 26, fourth year 29 It is evident in so far as these and other statistics go, that something in the way of definiteness is beginning to appear as to the year in which botany is taught But it is also to be noted that in these schools botany appears in almost every possible relation to the other sciences that are taught, and it is taught by teachers who teach almost every possible combination of subjects in the entire curriculum The sciences need more of the same sort of consecutiveness that is found in the languages, if we are to develop more worthy scientific value

Furthermore, from the above-mentioned investigation and others, it appears that the courses in botany vary in nature from systematic botany to a study of the anatomy and cytology which deal with plant evolution Surely the courses in secondary schools need scientific study, unless it is true that there is no part of the subject and no particular organization that is best for the education of beginners I believe we have a right to expect that a scientific organization of the science for the secondary schools, in addition to conferring better immediate results upon pupils, will lead more of the students who have done well in science to desire to continue these studies in college This would be of great advantage, for we need more students who early in life have begun to *think botany* and to think in the scientific method

The nature of the preparation of our graduate students is also a factor in our product This varies largely In at least some of the larger universities comparatively few of the graduates come from the local undergraduate body They have for the most part had their training in the smaller colleges, and those who come to the university are of two classes—those who are called, and those who are sent Some of them, through the more general courses of the smaller colleges, got their desire and enthusiasm for botanical investigation, and come to the university to continue that study They are chiefly those who give us new botanical knowledge Others, who have not secured suitable positions, come to the university and do graduate work as a means of securing better employment, and good botanists and good teachers sometimes develop from this group A compelling desire to study botany is the motive most likely to yield results of high order

3 Another factor in the efficiency of our student product is found in the nature and appropriateness of the courses into which these students go when they come to colleges Whether research or teaching is the end to be secured, there are needed courses in the general fundamentals of plant life and structures, and in chemistry, physics, physiography and general physiology Too early specialization is likely to produce a narrow research student, and to render a teacher unable to give to his students the necessary vitality in his introduction to general botany In our revolt from the special field of systematic botany, botanists went to an extreme of even greater specialization, so that sometimes students in research in morphology are uninformed regarding the relationships of the particular plants with which they work And so specialized are we at times that teachers in small colleges and secondary teachers who have had our so-called general courses must teach a special field of botany because they know no other It is quite possible in some cases to go into a secondary-school class in botany and by observation of the nature of the teacher's work, to determine the university in which the teacher was trained This, of course, is not an argument against research in which we all believe most pro-

foundly, nor against emphasis upon special lines of research in different universities, but is an argument against permitting that special research to dominate courses that presumably are for general education in botany As Schleiden in 1849 organized the general field of botany as an inductive science, we again need for general students a presentation of the fundamentals of the science as a whole

There are many other factors that have to do with the efficiency of the product of our botanical teaching We need more students who in their latter college years have definite purposes in mind—as teaching, research, practise of forestry, agriculture, etc Possibly our teaching ought to enable them to discover purposes that will absorb them as do other college interests

More fundamental, however, is the fact that we have been too content to assume without sufficient data, and to dictate regarding the nature of the needs of general instruction in our subject rather than to make the same sort of investigation in the field of teaching that we should make in our botanical investigation If we can devise methods of making a scientific study of botanical education, we can improve our student-product

O W CALDWELL
UNIVERSITY OF CHICAGO

III METHODS OF BOTANICAL TEACHING

As a past master in the art of cooking botanical hares, Dr Bessey has spent most of his time in elaborating the recipe To me, however, the problem seems peculiarly one of making sure of getting the hare and then of keeping it long enough to cook it properly. As I see the problem, it seems almost imperative that the hare should be caught in the high school The chief difficulty in our getting material for turning into young botanists lies at this point. High-school students, and especially the boys, are not attracted to botany, one might say they are not attracted by the kind of botany offered More than that, and this may be the crux of the whole question, we fail signally to enlighten the parents of the boy as to the real meaning and place of botany Botany will not attract the attention of the high-school boy unless it meets every-day conditions—unless it puts him in touch with his every-day environment in a way that is sympathetic as well as illuminating Moreover, it is perhaps of equal importance to bring the public to understand what a fundamental place the knowledge of plants has in every-day life, and how important a part of education it is in consequence

So far as the high school is concerned, we have the situation entirely in our own hands Few of us can teach anything but what we have been taught, nor can most of us teach in any way but the one by which we have been taught If you will look over the high schools of your state you will see that the kind of botany you are teaching is the kind of botany that is being taught in your high schools. It seems to me that few botanists realize this fact It really means that we are actually teaching high-school botany to our beginners, for this is inevitably the botany that they will carry into the high schools When we appreciate this fact thoroughly, we shall change our elementary teaching When we do change it in a way to attract the sympathy of our students, then the problem of catching the hare, or at least of knowing the paths that he will follow, will be solved

The next most advantageous point for catching botanical hares is upon entrance to college This last year, in the University of Minnesota, the College of Arts graduated 265 bachelors—most of them maids. There were 195 of the latter and only 70

men Out of the 265, thirty-five had taken a major in science, for many of the thirty-five, this meant but three courses in science during the whole college course This tells definitely, it seems to me, of our failure to attract freshmen to science This failure is largely our own fault It is the failure of botany to provide a definite avenue to a position, such as is offered by courses in law, medicine, engineering, agriculture and forestry The boy does not enter botany, because he knows of no such opportunity in it There is no definite course set forth in the catalogue for the training of professional botanists, such as we find everywhere in colleges of agriculture, engineering, etc

Our second failure, and the most significant one, it seems to me, is to hold our hare long enough to make a plausible instructor of him—to make even the beginner that Dr Bessey has in mind, one who knows enough to find out what he must do to learn how to bud pecan trees It seems to me the signal failure we are all guilty of in teaching elementary botany is the failure to catch the students' point of view—of realizing that it is what the student needs and likes in his own peculiar environment that must determine, the method of teaching and the matter that we use I can not see that the materials for our courses should be assembled, as they have been, from the standpoint of the professor, upon the obvious assumption that what the professor likes to teach the student is the best thing for him to learn This seems to me the chief reason why we fail to hold students in any considerable number for advanced work Naturally, this does not apply to the two or three universities which attract students from all over the country for graduate work It concerns the majority of botanical departments, however, in which the hope of advanced students must be realized chiefly from the beginning classes

To become concrete, it would seem that the microscope is responsible to a very large measure for our difficulty No hard-headed boy of freshmen age expects to carry a microscope around in his pocket throughout his life He is interested in things that go and things that work, and I believe that we shall get his sympathy and interest and succeed in holding him for advanced work only as we give him what he wants and needs in this respect Last year a freshman girl opened our eyes somewhat more widely on this very point She was working with the germination of seeds in the greenhouse, after describing the steps in germination, she added naively as an afterthought, "the seeds we worked with were real peas such as you see on the table" The microscope has made the student feel that he is dealing with an unreal world, and that the plants we use in botany are none of them of the least importance in every-day life Not only is the microscope far too special an instrument for the beginner, but this specialized tendency also permeates nearly all elementary botanical teaching I recently encountered a sentence which will illustrate this fact It is taken from a book which "is addressed to pupils in their first or second year in the high school" The sentence is the following

> The change from free parts of hypogynous flowers to union of parts as shown in perigynous, epigynous, epipetalous, sympetalous and synsepalous flowers, reaching the climax in the composites

I find it difficult enough to get such ideas into the heads of college sophomores, with any real understanding of their meaning In the case of high-school students, it indicates clearly that we are shooting far over their heads While I admit that a good drill-master can make a student memorize

a statement like this, I feel that it is practically impossible to give him any real understanding of the many concepts in it, in any beginning course We succeed in making our beginners feel, as a consequence, that botany is nothing but a lot of long hard names

Now what is the remedy for the dearth of advanced students? In the first place, I recognize fully that we will hold students for advanced work only as we gain their interest and sympathy in the general courses The test of our general courses in college botany must be—what does the student need, and what must he use in everyday life To many of you this practical outlook upon the subject seems to be in conflict with what we call a scientific presentation To me, scientific botany means presenting the important facts about plants from the standpoint of their everyday behavior and use, in a thorough, accurate and systematic fashion While it is a time-worn truism to say that we must proceed from the known to the unknown, yet we must realize that no one ever succeeded in learning in any other manner We must take the student in his every-day plant environment, set him to work puzzling about it, and point out the way by which he can solve his own puzzles I think it is as unfortunate as it is illogical, that our education should be built upon the assumption that the early years are for memorizing, and the later years for reasoning Until parents and teachers have stifled the spirit of curiosity, which is only the research spirit in an earlier form, the child is constantly reaching out for new experiences, asking endless questions, and taking endless clocks and dolls to pieces I will admit that this spirit of inquiry has almost disappeared by the time the student enters college, but it can be fanned into an active flame again in many cases Still more important than this, however, is to find a way to keep it alive

For the most practical of all remedies, we must give our attention to the difficulties arising out of the fact that the school year runs the wrong way around If the student is to deal with live plants, with plants as agents and materials in every-day life, as he must to be interested and benefited, we must realize that these things can be obtained only by the most careful planning We must not only find means for stretching the plant season at both ends, in the spring and in the fall, but much more important still, we must confront the fact that beginning botany can not be properly taught without adequate greenhouses, as well as gardens The greenhouse means constant contact with the most interesting and the most useful plants throughout the whole school year It lends itself readily to the task of bringing the student into touch with the uses and applications of plants in a natural way Indeed, the most indispensable feature of real botanical study, that of independent first-hand work with the living plant, is hardly possible without adequate greenhouses The every-day relations between man and plants are of vastly more importance than all of the other things that we teach under the name of botany They will not only crowd to overflowing the two years of beginning botany, but they will fill up a large part of the advanced courses

One of our most signal failures arises from our feeling that a record in the form of drawings or notes constitutes knowledge—that the record indicates that the student really understands what he is recording Nothing is further from the truth, as a rule The record has no value, indeed, it rather does harm, except to indicate to what extent the beginner observes correctly and thoroughly As something to be

crammed for quiz or examination, it is downright pernicious, hence the formal record should be reduced to a minimum, and the real emphasis laid upon first-hand contact with live plants, correct and thorough observation, and independent reasoning

Again, as botanists familiar with an enormous amount of detail, we try to make the college course in botany cover just as many things as possible One can admit that it should do this in so far as it can, and still realize that it can do this in only a small degree Nearly every course, and every text-book without exception, contains several times as much matter as the student can assimilate Indeed, if we remember that we ourselves learn little except by experience and experiment, we shall see that this must apply much more forcibly to beginners in botany For this reason I do not believe in text-books, or in lectures in any general course whatsoever, I would have none of them This no longer seems to be a mere opinion, but the logical conclusion from actual and definite experiments in teaching botany Listening to talks about plants can not lead to real learning in any sense of the word, and reading about them is in some respects worse rather than better, so far as the beginner is concerned

I would replace text-book and lecture wholly by first-hand contact with plants I would do away with all set quizzes and examinations, and make the student face the test of his work just as often as he faces the work itself Moreover, even by this method, students can learn little by single contact To take up a plant or a function or a structure once, and then to leave it, not only wastes time, but it also fixes an unfortunate habit A tandem arrangement of materials and courses can never give the beginner real understanding Every course should telescope the one before it, touching the major points again and from different angles, broadening and deepening the student's knowledge upon a sure foundation, not upon the mere assumption that he recalls or understands anything that he has had

To some teachers the universal remedy for lack of knowledge or understanding on the part of the student is what is called the intensive course The latter has certain apparent advantages One covers more ground, without question, and the student's handling of the subject matter seems a little more certain The real test of an intensive course, however, can be made only by unexpected quizzes at intervals of a month or two after the course has been completed Any one who applies such a test to an intensive course will need no further argument in regard to it One who has applied such a test can not feel like giving any more time to discussing its value

I wish to emphasize the point Dr Bessey has made as to the need of using young botanists just as early as possible We are now trying out a plan by which sophomores, who plan to specialize in the subject, are put in charge of small groups of freshmen in greenhouse work The plan during the first year has proved much more successful than we anticipated, and it will be extended just as rapidly as possible It has been a splendid thing for the sophomores, and it has not proved fatal to the freshmen

I can not close without pleading that we make the teaching of botany a matter of experiment We should be ecologists who study the student, the method, the matter and the results, both as to knowledge and to training, in an exact, quantitative manner If we do this, we shall get rid of our loose opinions that for the beginner in bot-

any any method is as good as any other method, and that the results must be good because *we* have done the work I feel sure that the use of experiment in connection with our methods of teaching, and the measurement of results will go a long way toward changing our present methods and improving upon our present results

F E CLEMENTS

UNIVERSITY OF MINNESOTA

DISCUSSION

Professor John M Coulter, University of Chicago

As Dr Bessey says, some of us began botany a good while ago, when facts were so few that they were pieced out with enthusiasm, and our knowledge of the subject was chiefly enthusiasm, but now the facts have multiplied so enormously that it is a problem how to present them

I have been in discussions of this kind for a good many more years than I should like to acknowledge They have all sounded alike to me, but the thing I learn from them is this that no matter how much thought we give to the technique of teaching botany, or how many devices we suggest as to methods of presenting it, a gratifying group of successful botanists continue to surmount all the obstructions we manage to place in their way My definition of a successful teacher has long been one who places the fewest obstructions in the way of the student

It is clear that we must encourage independence and originality in our students if they are to become investigators or only teachers This attitude is appearing in the teaching of botany, for teachers are becoming more independent, and are thinking more for themselves No teacher, however successful, has the right to prescribe for others a detailed method of teaching It is only a stupid teacher who copies some other teacher Every one must have his own way, and if the text-book is the only way for him, let him use it, if he can do better without it, let him throw it away

In brief, the problem is this We are confronted by all sorts of suggestions as to teaching Our subject has grown to be so vast and is still growing so rapidly that we know not how to deal with it in detail There are just two general things that a teacher must keep in mind, and the details can be left to shift for themselves

In the first place, there must be developed a general perspective of the subject It is a vast plexus, and each of us in his own individual way must develop for the student some conception of the extent and interrelationships of this plexus we call botany, so that he may leave us with no narrow vision

In the second place, in addition to the perspective, there must be developed what we call the scientific method, which is a certain attitude of mind This is absolutely fundamental There are many ways of doing this and every teacher has his own way of enforcing the training that demands the truth, and knows what it takes to reach the truth

It is my conviction that any one cultivating this perspective and this scientific attitude of mind, by whatever detail of method they have been reached, is likely to prove successful in any form of botanical activity, whether it be teaching or investigating, with the scientific motive or with the practical motive The details have become too numerous to include in instruction, but it will always be possible to train a spirit that will be able to master any details

Professor F C Newcombe, University of Michigan

I will say that I feel considerably cheered up since the last two addresses No doubt

the rest of you, or some of you, feel the same way I was beginning, a few minutes ago, to congratulate myself that such instruction as I had received was received twenty-five years ago instead of at the present time, because I know that if it had been received at the present time I could have become nothing but some poor ignoramus

First of all, I should like to refer to some of the ideas presented here this evening

Professor Bessey stated that our students in the university are looking here and there without reference to any aim in life, and I wondered whether he had actually looked into the matter of student elections in his university, where elections have been quite free, as they are in the university with which I am connected, or whether he has been seriously investigating this subject The matter has been looked into in my university, and there it is found that more than 80 per cent of the students who have perfect freedom in elections have elected with some aim There is a comparatively small percentage of students who are browsing around without taking any direction

The second thing that Dr Bessey says is that he is trying a system of instruction in his university of 20 to 25 hours in botany as preparation for a college or university instructorship That is the minimum we in Michigan think the average student should have for preparation to teach botany in the high school

It was said a few minutes ago by Dr Coulter that it is not a matter of the number of hours the student spends on a subject, but it is the ability which the student develops for doing things, his attitude, his efficiency, his originality, that makes him able to advance I had some years ago a student who took only one year in botany. She was a teacher, and she had been teaching for some time, and I gave that woman the strongest recommendation of any woman who went out that year She had only one year, and yet she was ready It is not how many courses the student has, it is a matter of the student's ability to take new ground, to start in a new direction and develop the subject for himself

On the side of research I can not help placing in contrast to the quantity of preparatory work which some of us think we must have from our students before coming to research, that well-tried system in the German universities with which you are all familiar, and which reduces the number of students to a few successful ones by the law of survival of the fittest You know that, in the German universities, the student takes perhaps on the average not more than one year in elementary botany, and is then allowed to go along for a few weeks, or possibly a semester with a *Vorarbeit*, and is then thrown mostly upon his own resources for investigation There are many successful botany teachers and investigators who come out of that sort of training. I wouldn't advocate that sort of training in this country, but I think there is danger of our overdoing the matter in endeavoring to give the student something of all kinds of knowledge in botany If the student is fit for any kind of teaching after he has had proper training in some lines of work he will be able to work out something for himself that he may not have been trained for in the schools

It was stated here also in one of the addresses that the aim of general education is not for research I think that statement was made I would not say that one aim of general botanical education is not for research What have we been talking about and hearing about in this session of scientific societies in Minneapolis? We have been hearing of the need of the in-

vestigation of plant physiology, of phytopathology, of the study of all things that are related to the welfare of the people of this nation and of the world. Now, if it isn't the university's business to prepare men for research, I should like to know where that business does lie.

It seems to me we have a double duty—we must provide teachers and we must provide investigators. The university's function is just as much for research as for instruction. The staff should be just as much bound to the doing of research as to the giving of instruction, and just as much bound to train the young people under them for research as to train them for teaching. We need both. We need research just as much as instruction.

Now, is it true, as was stated here, that there is no open door to a career in the study of botany? It was said of law, medicine, etc., that there is an open door. But at the present time we can say to the student, there is also an open door in the study of botany. What does it mean when Dr. Bessey says they can not supply the demand? We have all of us felt that same thing. It means that, although the remuneration is not adequate in many directions, still there is the open door toward the earning of one's livelihood at least.

Now, to take up quite a different matter, and that on the main subject that this discussion opened with; that is, the question as to why we do not have more students becoming professional botanists. That's what the meaning is, I think, of the question as it was put. Now, the case is not so bad as has been presented here. If you will pardon me, I will review the relations at our own institution. We have no agricultural college at the university. We have a first-year class of 200 students—I think 194 this year; we have, besides that, in our classes above the freshman year, 175 students. Now, that proportion does not seem to me to be bad at all. We have our advanced classes with ten students, fifteen students, one class with thirty-two students, another one, second-year students, or mostly of second-year students, with fifty-five, and to my mind the proportion is not bad and it does not call for any great alarm as to the future. I expect in the future that the proportion of students in the advanced class will tend to increase instead of diminish. I don't see why it should not.

I find the method of encouraging the promising student to go on with the work is justified. We all make mistakes, but nevertheless we can, with ordinary good judgment, read the case right four times out of five, and perhaps more often than that, and I have found that by advising with those who attract attention as capable students, one can usually find several who can be led, without very much persuasion, in the direction of becoming professional botanists. One thought that is on a different matter. I have been considering for two or three years whether, as teachers of high-school teachers, we ought not to change somewhat—I know it is already done in Minnesota—whether some of us ought not to change our methods so that the perspective of the high-school teacher is brought more into relation with his subject matter as it occurs in nature. Of course, a great deal can be done by greenhouse study, but after all that does not take altogether the place of field study, and I believe we must draw these teachers to field study so that when they go out to teach botany in the schools they may show their pupils the way by which they can in themselves carry the work further than it is carried in the schools—the high schools and lower grades.

I would like to see a set of statistics from

which I could ascertain how many of the professional botanists—those who have passed out from under our hands within the past ten or fifteen or twenty years, or longer—how many of these were young investigators before they went to the high school I will venture to guess that I could pick out in this room fifteen or twenty of the men who sit right here whose youth I know something about, who made collections of plants and insects and hammered up rocks to get the fossil shells out of them before they went to the university or came within three or four years of it

If statistics should bear out my belief, we should find that most scientists are so born and not given their bent by training, and that the few turned by training in the direction of professional science are thus influenced by the teacher who knows how to make the student an investigator at the same time he is pupil

---

LEONARD P KINNICUTT

IN the issue of SCIENCE of February 17 there appeared a brief notice of the death of Professor L P Kinnicutt, director of the department of chemistry in the Worcester Polytechnic Institute

Leonard Parker Kinnicutt was born in Worcester, May 22, 1854, the son of Francis H and Elizabeth Waldo (Parker) Kinnicutt He received his early education in the schools of Worcester, graduating from the high school in 1871 He went at once to the Massachusetts Institute of Technology, where he devoted himself chiefly to the study of chemistry. Following his graduation, in 1875, with the degree of bachelor of science, he spent four years in professional studies in Germany At Heidelberg he came under the inspiring influence of Bunsen from whom he acquired an appreciation of the value of careful and accurate analysis Here also under Bunsen's guidance he was initiated into the refinements of gas analysis. This was the period when organic chemistry was developing with tremendous rapidity especially in Germany. Bunsen had passed the zenith of his career and was not in sympathy with the new tendency which was manifesting itself in chemistry It is not surprising then to find the young Kinnicutt leaving Heidelberg and matriculating at Bonn Only ten years before, Kekulé had been called to the University of Bonn to take charge of the newly built laboratory, which at that time was the finest in all Germany and after which later laboratories were patterned Kekulé's was a charming personality His lectures were a model for simplicity of arrangement and clearness of presentation, and the experimental demonstrations were carried out with such fascinating ease and dexterity that the young Kinnicutt was captivated by the spirit and beauty of organic chemistry and devoted himself diligently to its study

He was fortunate in being accepted into the private laboratory of the master, where he became associated with Richard Anschutz, the present director of the Chemical Institute at Bonn In collaboration with Anschutz he published a number of papers, chiefly on phenyl-glyceric acid This association ripened into a lasting friendship Returning to the United States in 1879, he spent a year in study with Ira Remsen at the Johns Hopkins University, and then three years at Harvard, where he served as instructor in quantitative analysis and as private assistant to Wolcott Gibbs, at that time Rumford professor of chemistry In 1882 he received from Harvard the degree of doctor of science and in September of the same year accepted an appointment as instructor of organic chemistry at the Worcester Polytechnic Institute In the following January he became assistant professor of chemistry, three years later he was made full professor, and since 1892 has been director of the chemical department.

As early as 1885 Professor Kinnicutt began to give attention to the question of sewage disposal and sanitary problems. He became an authority on the sanitation of air, water and gas, on the methods of analysis and on the disposal of wastes He paid particular atten-

tion to the examination of water and watersheds and the contamination of rivers and ponds by trade wastes and sewage He made numerous reports, both as regards private and public water supplies

He visited England on an average every other year since 1894, familiarizing himself with the work done in that country and the results were embodied in various articles which he published on the subject He paid special attention to the subject of the pollution of streams by wool-washings, and made a careful study of this problem at Bradford, England, where a greater amount of wool is washed annually than in any other city in England or in this country

He was employed as an expert in numerous cases regarding the pollution of streams and ponds, and was one of the experts in the case of the pollution of the Mississippi River at St Louis by the sewage of Chicago In 1903 he was appointed consulting chemist of the Connecticut Sewage Commission, a position which he retained up to the time of his death He was a frequent contributor to scientific periodicals and the proceedings of learned societies upon topics relating to his specialty

In 1910, in collaboration with Professor C E A Winslow, of the Massachusetts Institute of Technology, and Mr R Winthrop Pratt, of the Ohio State Board of Health, he published a book entitled "Sewage Disposal" which is considered to be one of the best treatises on the subject of sewage disposal in the English language

Professor Kinnicutt's reputation was not confined to this country He enjoyed a wide acquaintance, both in England and on the continent, and possessed the rare faculty of keeping ever fresh and active a friendship once established One of his highest honors was the appointment as president of the Section of Hygiene of the International Congress of Applied Chemistry, which is to be held in Washington and New York in September, 1912 Even to within a few days of his death he continued to work with characteristic zeal in perfecting plans for the success of the section over which he was to preside Professor Kinnicutt was deeply interested in the sanitary problems of his native city, Worcester. He kept a careful watch upon the city's water supply During the "water famine" of the present winter, from his sick-bed he directed the tests to be made, had daily reports brought to him and outlined the policy by which, in his opinion, the city's health might be best safeguarded

He devoted a great deal of time and money to secure a pure milk supply in summer for the babies in needy families, and at the time of his death he was a member of the Worcester Medical Milk Commission, which is investigating the question of pure milk for the city Professor Kinnicutt was widely connected with scientific associations, he was a fellow of the American Academy of Arts and Sciences, a fellow of the American Association for the Advancement of Science, of which he was vice-president in 1904, a member of the American Chemical Society, and president of its Northeastern Section in 1902, and councillor for a succession of years, a member of the Society of Bacteriology, a fellow of the New England Water Works Association, of the Boston Society of Civil Engineers; of the American Antiquarian Society, and of various foreign associations, including the Association of Managers of Sewage Disposal Works of England, the London Chemical Society, and the German Chemical Society He was a member of several social clubs in Worcester and Boston and retained to a remarkable degree his interest in the alumni reunions of the Massachusetts Institute of Technology, of the Johns Hopkins University and of Harvard University, and he rarely failed to be present and add his geniality to the general good cheer.

Esteemed and honored by the scientific world, and beloved by a wide circle of acquaintances, yet it was as a teacher that the true worth of his character manifested itself Possessed of a broad training and knowledge of his subject, and a fund of personal experiences, with which he punctuated his lectures, he was enabled to drive home the truths which he desired to impress on the minds of his stu-

dents. Interest in his students, however, did not cease with the lecture or the laboratory. He was ever ready to listen sympathizingly and indulgently to those students who were in distress, and to all such he gave liberally of his time and purse. This conscientious devotion to duty and unselfish human interest endeared him to the students and alumni. It came as a great shock to all when, after a delightful summer of European travel and the resumption of his academic duties, apparently in his usual good health, he was attacked by a slow fever which confined him to the house after but a few days of activity. The trouble was diagnosed finally as tuberculosis. He received his first warning that he had this insidious disease in his system when he was a student in Germany, but had apparently fully recovered from this earlier attack. It was hoped that a year's leave of absence and careful nursing would restore him to health and the resumption of a part at least of his former activities. Toward the end of January, however, his heart became seriously affected, and he failed rapidly until the end came peacefully on the morning of the sixth of February.

Professor William T. Sedgwick, a lifelong friend and one of the pallbearers at his funeral, paid a fitting tribute to his memory when he said, "His was a unique, lovable and altogether charming personality. Kindness and friendship such as his life exemplified could no further go. He was critical, yet just, fearless yet considerate of others, honest to a fault, a hard worker, and to a degree nowadays unusual, an accomplished and cultivated gentleman."

W. L. Jennings
Worcester Polytechnic Institute

HENRY PICKERING BOWDITCH

The following memorial note on the life and services of Professor Henry P. Bowditch has been prepared for the American Physiological Society by a committee of its members.

At the death of Henry Pickering Bowditch there passed away a man who had notable influence on the development of medical and biological science in America. He was born in Boston, April 4, 1840, and was graduated from Harvard College in 1861. As a graduate he began the study of chemistry in the Lawrence Scientific School, but left, in November, 1861, to become second lieutenant in the First Massachusetts Cavalry, then starting for the front. After loyal and chivalrous service to his country during the remaining three and a half years of the Civil War, he resumed his studies in Harvard University and received, in 1868, the degree of Doctor of Medicine. Thereupon he went to France and Germany to learn from the masters of his chosen science, physiology, the aims and methods of research. Filled with the spirit of Bernard and Ludwig, he returned to the Harvard Medical School in 1871, and established the first American physiological laboratory for the use of students, a laboratory which soon proved hospitable to investigators in every phase of experimental medicine. For thirty-five years he was an energetic and inspiring teacher, and a leader in investigation. His studies of the peculiar functions of cardiac muscle, the indefatigability of nerves, the knee-jerk and conditions affecting it, the force of ciliary activity, and the growth of children, illustrate the range and originality of his researches. Apparatus invented by him and widely used in physiological laboratories attest his mechanical ingenuity. He was one of the founders of the American Physiological Society and was its second president. The traditions of the society, particularly its character as an association to encourage research, are largely the result of his initiative. His example and his genuine appreciation of new work as it was reported at meetings of the society were a wholesome stimulus to young men beginning physiological investigation.

To the larger interests of medicine he rendered important service by promoting reforms in medical education, notably by advocating and helping to introduce the four years' required course, and later by strongly urging greater freedom of election in medical study. The Harvard Medical School he served as Dean for a decade of important growth, and the development of the school will long con-

tinue in directions which his wisdom foresaw Among the most valuable of his activities was his repeated defense of animal experimentation against unreasonable legislative restrictions, an activity in which he secured victories likely to preserve freedom of medical research for many years to come

The honors received by Dr Bowditch were many He was a member of numerous learned societies in this country and abroad He was a doctor of science at the University of Cambridge, and a doctor of laws at Edinburgh, Toronto, Pennsylvania and Harvard In 1900 he was president of the Triennial Congress of American Physicians and Surgeons

With sure and sober judgment Dr Bowditch combined vigor and readiness of action which made him a natural leader He was a neverfailing source of stimulation and encouragement to all progressive movements aimed at professional and civic improvement, and his mind was fertile with ingenious and effective ways to secure the accomplishment of worthy ends These qualities of leadership were combined with other qualities--keen interest, unfailing courtesy, fairness and good will--that won for him not only the friendship and lifelong devotion of the foremost men of medical science in this country and abroad, but also the affection of his students and close associates From the days of his youth, when he began the struggle for ideals, to his last years of failing strength, he met what life brought him with courage and cheerful humor, and he passed away as much loved for the beauty and strength of his character, as he was admired for his achievements

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

The council met at the Cosmos Club, Washington, D C, on Tuesday, April 18, 1911, at 5 P M

Mr Minot reported the following from the Committee on Policy

1 To recommend to the council that it look with favor upon the holding of a Pacific Coast meeting in the summer of 1915 and of extending this meeting to the Hawaiian and the Philippine Islands

2 To recommend to the council that it (the council) recommend to the next general committee that the meeting of 1913–14 be held at Atlanta, Ga, postponing the proposed meeting at Toronto until a later year

The council adopted the above resolutions

The secretary of Section I reported nominations of officers for that section as follows

Vice president and Chairman—Oscar P Austin
Secretary—Seymour C Loomis

These nominees were elected

On motion by Mr Cattell, the permanent secretary was instructed to inform the officers of the societies usually meeting with the American Economic Association that the American Association would view with pleasure closer relations between this association and these societies and would be glad to have them represented upon our council

The permanent secretary made announcement as to the preliminary work which has been accomplished so far by the local executive committee for the Washington Meeting

It was suggested that it would be advisable to instruct the secretaries of the sections, prior to the long vacation, concerning the general interest sessions

Messrs Minot and Welch were appointed as a committee of the council to ask President Taft for some official recognition of the coming Washington meeting

SCIENTIFIC NOTES AND NEWS

At the meeting of the National Academy of Sciences on April 20, the following were elected to membership Edward Emerson Barnard, astronomer, Yerkes Observatory, Williams Bay, Wis, Edward Burr Van Vleck, professor of mathematics, University of Wisconsin, John Fillmore Hayford, director of the College of Engineering, Northwestern University, Edwin Herbert Hall, professor of physics, Harvard University, Julius Oscar Stieglitz, professor of chemistry, University of Chicago, Bertram Borden Boltwood, pro-

fessor of radio-chemistry, Yale University, James Furman Kemp, professor of geology, Columbia University, Arthur Louis Day, director of the Geophysical Laboratory of the Carnegie Institution, Robert Almer Harper, professor of botany at the University of Wisconsin Foreign associates were elected as follows Professor Ernest Rutherford University of Manchester, England, Professor Vito Volterra, University of Rome, Italy At the annual dinner of the academy on April 10 the Draper Gold Medal was presented to Mr C G Abbot, of the Smithsonian Institution, for his researches on the infra-red region of the solar spectrum and his accurate measurements, by improved devices, of the solar "constant" of radiation

DR ALEŠ HRDLIČKA, of the U S National Museum, has been made a corresponding member of the Société des Americanistes de Paris, and a foreign associate of the Società Italiana d'Antropologia

DR J S FLETT has been appointed to succeed Dr J. Horne, F R S, as assistant in Scotland to the director of the Geological Survey

MR FRANK M CHAPMAN, of the American Museum of Natural History, has sailed from New York for Colombia, South America, where he is to join Mr William B Richardson, who has been in that locality collecting birds and mammals for the museum for several months Mr Chapman expects to get into a region where no collecting of birds has been done, there he will make a systematic survey, probably obtaining some undescribed species and many new to the museum collections He will also get material for several new bird groups He has taken an assistant and expects to remain until July, when Mr Richardson and the assistant will continue the work

DR ELLSWORTH HUNTINGTON, of the geographical department of Yale University, is at present making explorations in New Mexico Mr Huntington is making his headquarters temporarily at Sante Fé in the old governor's palace, now used as the Museum of the Archeological Institute of America The field of exploration will cover the old Pueblo ruins and cliff dwellings

MR W A ORTON, pathologist in the Bureau of Plant Industry, Washington, sailed on April 22 for Hamburg, and will spend six months in the study of plant diseases and the sugar beet industry in Germany, Austria, Russia, France and England He will attend the fourth International Conference on Genetics at Paris and present a paper entitled "The Development of Disease-resistant Varieties of Plants"

DR YANDELL HENDERSON, of Yale University, is to make, during the coming summer in company with Drs Haldane and Douglas, of Oxford University, an extensive exploration around Pikes Peak, for the purpose of studying the effects of high altitudes on men and animals

PROFESSOR EDUARD SELER, of Berlin, on leave of absence in Mexico, has discovered a set of ancient paintings on the walls of one of the apartments of the Palenque Palace

THE Prince of Monaco has appointed as members of the first council of the new Institute of Human Paleontology in Paris MM Salomon Reinach, Boule, Berneau, Cartailhac, Capitan, Villeneuve, for France, Sir Ray Lankester for the British Isles, Professor von Luschan for Germany, Professor Hoernes for Austria-Hungary, Professor Issel for Italy, and Professor G Retzius for the Scandinavian countries

DR A E KENNELLY, of Harvard University, has accepted an invitation from the University of London to deliver a short series of lectures in London, at the end of May next, on "The Application of Hyperbolic Functions to Electrical Engineering Problems"

PROFESSOR FRANCIS E LLOYD, of the Alabama Polytechnic Institute, has recently lectured before the staff and students of the departments of botany and zoology of the Johns Hopkins University, on "The Behavior of Tannin in Persimmons during Ripening"

ON the evening of April 10, Dr. Wallace W. Atwood, of the University of Chicago, gave an illustrated lecture before the Geographic So-

ciety of Chicago on the "Mesa Verde National Park." It was a geographic study of the home of the cliff dwellers.

A recent meeting of the New York Academy of Medicine was devoted to addresses commemorative of the life and work of Dr. Edward G. Janeway. Dr. Francis Delafield spoke of him as the "Physician", Dr. William H. Welch as the "Pathologist", Dr. Abraham Jacobi as the "Consultant," and Dr. Joseph D. Bryant as the "Colleague and Friend."

At the coming meeting of the Medical and Chirurgical Faculty of Maryland, portraits will be presented of the late Dr. Francis Donaldson by Dr. William H. Welch and of Dr. Charles M. Ellis, Elkton, by Dr. Lewellys F. Barker.

English journals announce the death of Mr. Charles du Bois Larbalestier, a leading authority on lichens, to whom the last edition of Leighton's "Lichen Flora" was dedicated, and of Mr. J. S. Slater, for many years principal of the Civil Engineering College, Sibpur, near Calcutta.

The United States Civil Service Commission announces an examination to fill four vacancies in the position of forest pathologist in the office of Investigations in Forest Pathology, Bureau of Plant Industry, Department of Agriculture, at a salary of $1,800 to $2,400 per annum. It is expected that the persons appointed to these positions will be assigned for the greater part of the time to duty outside Washington, in charge of branch offices. Applicants will be required to show that they have had a broad scientific training, as well as considerable successful experience in technical or executive capacities. It is also desirable that they have training in plant pathology and botany equivalent to that required for the Ph.D. degree. The examination is open only to men, and competitors are not required to appear at any place for examination.

Beginning on July 5 and continuing during the months of July and August, the facilities of the Seed Laboratory of the Bureau of Plant Industry, U. S. Department of Agriculture, Washington, D. C., will be available, as far as space permits to any one wishing to become familiar with the practical methods of seed testing. There will be an opportunity to observe the laboratory methods of testing for germination and mechanical purity, including the recognition of crop seeds and the commoner weed seeds.

The *British Medical Journal* states that the first meeting of the International Committee of the seventeenth International Medical Congress would be held in London on April 21 and 22. The president of the committee is Dr. Pavy, the general secretary, Dr. Burger, of Amsterdam, and the members are Professors Waldeyer and Posner, representing Germany, Genaro Sisto, Argentina; von Eiselsberg, Austria, Déjace, Belgium, Rousseff, Bulgaria, Rovsing, Denmark, Ruffer, Egypt, Recasens, Spain, Musser, United States, Blondel, France, Kalliontzis, Greece, Koloman Muller, Hungary, Maragliano, Italy, Kitasato, Japan, Fonck, Luxemburg, Uchermann, Norway, Pel, the Netherlands, de Mattos, Portugal, von Ott, Russia, Subbotic, Servia, Henschel, Sweden, Cérenville, Switzerland. In addition to these, the following are members of the committee: Dr. von Grosz of Budapest, as general secretary of the previous congress, Sir Thomas Barlow and Dr. W. P. Herringham, of London, as president and general secretary respectively of the forthcoming congress, and Dr. Lucas-Championnière, of Paris, as president of the International Medical Press Association. The committee will have brought before it for approval the resolutions passed by sections of the sixteenth congress. It will also consider the date of the eighteenth congress, arrange the number and nature of the sections, and discuss a general regulation as to the organization of the congress and its position in regard to international specialist and national congresses. In this connection the general secretary of the committee, Professor Burger, will present a report on a series of proposals made by Professors Waldeyer and Posner. We understand that a proposition will be made to the com-

mittee that the date of the congress shall be changed from July 29 to August 6, as previously fixed, to August 4 to 9, 1913

THE local committee of the American Society of Mechanical Engineers, E M Herr, chairman, Elmer K Hiles, secretary, having in charge the preparations for the convention of the society, which will be held in Pittsburgh, Pa., from May 30 to June 2, inclusive, has nearly completed the work of arranging the program for each day during the meeting It has been settled that the arriving guests will be received and registered at the Hotel Schenley, the society headquarters, on Tuesday morning, May 30 In the evening there will be an informal reception for the members and ladies in the parlors of the hotel The extensive alterations being made by the new management of the hotel will add very largely to the comfort and enjoyment of visitors during the convention The professional sessions will be held in the lecture hall of the Carnegie Institute, near the headquarters, Wednesday morning and evening, Thursday and Friday morning In the meantime there will be a number of inspection trips to various industrial plants in the vicinity, a boat excursion for the members and ladies up the Monongahela River, a reception and ball at the Hotel Schenley on Thursday evening and, finally, on Friday evening, a smoker and entertainment, given by the Engineers' Society of Western Pennsylvania in their rooms in the Oliver Building A carefully prepared program for the entertainment of the lady visitors has been arranged by a committee of ladies from Pittsburgh and vicinity, which includes a number of social functions Judging from the number of inquiries, which have already been received from expected guests, a very large attendance is looked for, and everything indicates that this meeting in Pittsburgh will be one of the most successful "spring meetings" the society has ever held

THE twenty-second season of the Biological Laboratory of the Brooklyn Institute of Arts and Sciences will be held at Cold Harbor, Long Island, from June to September The regular class work will begin July first and continue for six weeks The courses offered include field zoology by Dr. H. E Walter, Dr C B Davenport and Mr. Sidney I Kornhauser, bird study by Mrs Alice Hall Walter and Mr G Clyde Fisher, comparative anatomy by Professor H S Pratt and Dr A A. Schaeffer, general embryology and microscopic technique by Miss Mabel Bishop, cryptogamic botany by Professor D. S Johnson and Mr H H York, plant ecology by Professor Henry S. Conard and Miss Ruth Higley, beginning investigation in animal bionomics, evolution, cryptogamic botany and ecology by instructors in those subjects A training course for field workers in eugenics is offered Twenty scholarships are available for properly qualified college graduates with biological training who wish to prepare for positions as field workers in connection with institutions and hospitals About two thirds of those receiving scholarships may look for appointments in such investigation A biological club meets two or three times a week during the evening One scholarship of a hundred dollars is available The announcement of the laboratory may be obtained by writing to the director, Dr C B Davenport, at Cold Spring Harbor, Long Island, N Y

ON April 11 Governor Tener sent a special message to the Pennsylvania legislature, recommending immediate legislation for control of the bark disease of the chestnut A bill has since been reported providing for a commission to undertake this work, and carrying a total appropriation of $285,000 So far it is only the eastern and southeastern counties of Pennsylvania that are completely infected with this disease, and it is hoped, by the elimination of spot infections in advance of the line of general occurrence of the disease, to restrict its spread to this area The great chestnut forests of the state which, according to the state department of forestry, have a total valuation of approximately $50,000,000, are still essentially untouched by the disease, and the great object of the proposed legislation is to save these Experiments made by the national department of agriculture appear to have demonstrated practical methods of quarantine

against this disease, and Pennsylvania is the first state to undertake these methods on a large scale

THE Association of American Geographers will publish, beginning with this year, an annual volume to be known as the *Annals* of the Association This will be devoted to the most important scientific papers presented at the anual meeting The publication will be managed by a committee composed of Mr Alfred H Brooks, of the U S Geological Survey, Professor Henry C Cowles, University of Chicago, Professor Ralph S Tarr, Cornell University, and Professor Richard L Dodge, Teachers' College, Columbia University

THE *British Medical Journal* reports that the principal centers in India in which plague occurred during 1910, and the deaths consequent thereupon, were as follows Bombay Presidency, 36,831; Bengal, 30,546, United Provinces, 144,266, Punjab, 143,416, Central Provinces, 42,104, Rajputana, 37,657, Burma, 7,605 The following are the most recent general statistics October 22 to 31, 1910, 5,641; November, 26,189, December, 39,604 Total deaths, 71,434, making, with deaths, July to October 22, 20,828, total for half year, July to December, 92,262 During the first six months of 1910 the deaths numbered 360,632 Total deaths during 1910, 452,894 It would appear that the recrudescence of plague in 1911 has begun in a more virulent form than in 1910 In January, 1911, the deaths from plague in India numbered 75,468 This is a higher figure than in 1910, when in January the deaths amounted to 51,437

UNIVERSITY AND EDUCATIONAL NEWS

BY the will of Henry F Dimmock, of New York, Yale University will receive about $100,000 and under certain contingencies will receive twice this amount

IN addition to the regular course in general surveying, the School of Mines of the University of Arizona will start this year a summer school of mine surveying lasting through the month of June This course, which will cover the details of underground surveying, the construction of stope plans and other allied subjects, will be conducted by Mr Eugene R Rice, engineer of the Hite Gold Mines, city engineer of Wickenburgh, etc. The work will be done in one of the numerous mines near Prescott, Arizona

DR ARTHUR H WILDE, who has been connected with Northwestern University, Evanston, Ill, since 1892 and has been secretary of the university council since 1909, has accepted the presidency of the University of Arizona, at Tucson, and will take up his duties there on May 1

DEAN JULIET GREER, professor of domestic science and art of the Oregon Agricultural College, announces her resignation from the position which she has held for three years, the resignation to take effect the coming July

RICHARD SWANN LULL, B S, M S (Rutgers), Ph D (Columbia), assistant professor of vertebrate paleontology in Yale College and associate curator in the Peabody Museum, was made professor of vertebrate paleontology in Yale University at the corporation meeting of April 17. At the same meeting Dr George Grant MacCurdy was appointed assistant professor of archeology He is secretary of the American Anthropological Association and of Section H of the American Association for the Advancement of Science

NEW appointments and promotions at Stanford University for the academic year beginning August 1, 1911, are as follows

New Appointments

Noah F Drake, associate professor of economic geology Dr Drake is a graduate, A B, A M and Ph D, of Stanford University, professor of geology and mining in Imperial Pei Yang University, Tientsin, China, since 1898

Mr Henry V Poor, instructor in graphic art Mr Poor received his A B degree at Stanford, 1910, and is now studying abroad

Mr Jesse B Sears, instructor in education Mr Sears received the A B degree at Stanford, 1909, now instructor in the University of Wisconsin

Mr Harry J Sears, Stanford, A B, 1910, instructor in chemistry.

Miss Alice E Berger, Stanford, A B, 1908, acting instructor in chemistry

Promotions

Robert E Swain, to be professor of physiological chemistry

Lillien J Martin, to be professor of psychology

John O Snyder, to be associate professor of zoology

Percy E Davidson, to be associate professor of education

Rufus C Bentley, to be associate professor of education

LeRoy Abrams, to be associate professor of botany

Clara S Stoltenberg, to be associate professor of physiology

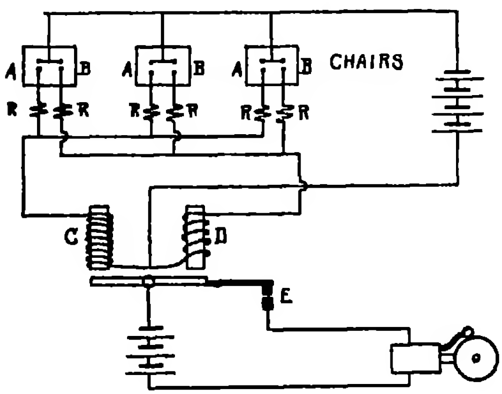
David M Folsom, to be associate professor of mining

Galen H Clevenger, to be associate professor of metallurgy

DISCUSSION AND CORRESPONDENCE

FACULTY BUSINESS ACCELERATOR

FOR the purpose of facilitating the despatch of business the following electrical device is suggested The method of operation will be evident from an inspection of the diagram of the electrical circuits All the chairs of the faculty room are fitted with electric circuits as indicated in the three chairs shown Each chair has two switches, those indicated by *B* are automatically closed when the chair is



occupied, those indicated by *A* are push-button switches concealed on the arm of the chair to be closed by hand *R, R, R,* etc, are suitable rheostats all of the same resistance It is evident that when any number of chairs are occupied the combined current through the switches *B* will excite the electromagnet *D* If the electromagnet *C* has twice as many turns of wire as *D* then, when a majority of those present at any meeting close the hand switches *A*, the magnet *C* will exert more pull upon the armature than *D*, thus causing the contact *E* to be closed and the bell to ring

The apparatus is not intended primarily as a means of taking formal votes but as an impersonal means of calling for the previous question In place of the bell it might be considered desirable to use an electric sign with the exhortation "*sit down*"

S

MUSEUM LABELING

ON the first two pages of the March issue of the *Museum News* of the Brooklyn Institute of Arts and Sciences are many ideas pleasing to those interested in museum labeling These stand out in contrast to some ideas with which museum men in this country, especially during the last decade, have been overwhelmed The art of label writing, as there stated, is truly a gift Many people fail to understand this and few realize that one must sometimes let an unsatisfactory label stand for a time, just as a minister sometimes preaches a poor sermon

The *Museum News* is almost an ideal example of what a museum newspaper should be It is dignified, conveys not only interesting but true information and also has a distinct tendency to cause the reader to wish to help not only the museums of Brooklyn, but the museums of the country

HARLAN I SMITH

WILKES'S ANTARCTIC DISCOVERIES

TO THE EDITOR OF SCIENCE The *Zeitschrift* of the Geographical Society of Berlin recently published a short notice[1] or review of my article "Why America should Reexplore Wilkes Land"[2] The reviewer finds fault with the article and attempts to straighten it out in the following words

[1] *Zeitschrift der Gesellschaft für Erdkunde zu Berlin*, 1910, No 7, p 469

[2] *Proceedings American Philosophical Society*, Vol XLVIII, 1909

Fur eine kraftige Wiederaufnahme antarktischer Forschung, und zwar in Wilkes Land durch Nord Amerika tritt Edwin Swift Balch mit Entscheidenheit vor Seine einschlägigen Darlegungen aber leiden durch die gänzlich ungerechtfertigte Annahme, dass die früheren Arbeiten der Nordamerikaner nicht nach Gebühr geschätzt, und in England ignoriert worden seien Das ist nicht geschehen Insbesondere hat die Fahrt von Wilkes an der Nordküste von Ost Antarktika immer volle Anerkennung gefunden, ist doch der Name Wilkes Land jenem Küstenstriche gegeben worden Aber Zweifel sind entstanden, da sich nicht alle Angaben von Wilkes als stichhaltig erwiesen haben Dies gilt insbesondere von den Angaben von Land auf einer Karte, welche Wilkes James Ross gegeben hat Bereits letzterer passierte am 6 Januar 1841 eine solche Stelle und fand hier tiefes Wasser, und seither hat Scott auf seiner Heimreise genau den Ort auf offener See passiert, wo Wilkes angibt, am 19 Januar 1840 3000' hohes Landgesehen zu haben Endlich hat E v Drygalski bekanntlich Termination Land nicht an der Stelle gefunden, wo es Wilkes es gesichtet haben will

In this short paragraph the reviewer makes five statements which call for an answer

1 and 2 The reviewer says it "has not happened" that the work of American explorers was ignored in England and also that Wilkes has had full recognition

In order to recognize the erroneous nature of these two statements it is only necessary to turn to many of the papers of Sir Clements R Markham, beginning with his article "Polar Regions"[3] and culminating in his article "The Antarctic Expeditions,"[4] in which he mentioned many of the more prominent Antarctic explorers, but ignored totally Wilkes's discovery of the mainland of East Antarctica and Palmer's discovery of the mainland of West Antarctica. Scott's various misstatements about Wilkes,[5] winding up in his silly assertion "thus once and for all we have definitely disposed of Wilkes Land," can also be cited as attempts at disparagement

Of course, some English writers are just and fair, and a shining example is Dr Hugh Robert Mill, who writes in accord with the evidence[6] and whose excellent work the reviewer might consult with profit

3 The reviewer repeats the old misstatement about Ross sailing over a part of Wilkes Land I supposed that I had killed that piece of fiction[7] and that Dr Mill had laid its ghost[8] This matter would take too much space for rediscussion here, and it seems sufficient to mention the fact that, as far as I am aware, my italicized statement "none of Wilkes's discoveries were disproved by Ross, for the simple reason that Ross never was within sighting distance of any part of Wilkes Land"[9] has never been challenged

4 The reviewer says that Scott passed "exactly the spot on open sea," where Wilkes states he saw land Now Scott makes no claim to sailing over any part of Wilkes Land On his return voyage, Scott sailed westward towards Cape Hudson, but when he got within about fifteen miles of where Wilkes had charted it—doubtless fifty miles too far north—Scott turned northward and sailed away A glance at Scott's chart[10] proves this absolutely and that Scott therefore did not disprove any of Wilkes's discoveries[11]

5 The reviewer says that Drygalski did not find Termination Land at the place where Wilkes said he had seen it. Now Wilkes, at the most westerly point of his memorable cruise along the northern coast of East Antarctica, saw appearances of land to the southwest and charted them as Termination Land. Then Drygalski on his cruise south discovered to the eastward a "high ice-covered land." And a comparison of the charts of the two explorers proves that Drygalski's "high

ice-covered land" must be the western edge of Termination Land

I explained this matter fully in an article "Termination Land"[12] That article was commented on in Germany at length by Dr Singer,[13] who concluded that there was no reason for leaving the name "Termination Land" off the charts, and who also published with his article an excellent map proving that Termination Land and Drygalski's high land are one It was also commented on by Dr H Wichmann[14] who stated likewise that there was no cause for taking the name Termination Land off the charts, and by Dr H Haack,[15] who wrote that Drygalski's assumption could not be kept upright That is to say, three leading German geographical authorities entirely agree with me as to Drygalski's high ice-covered land being Termination Land

EDWIN SWIFT BALCH

SCIENTIFIC BOOKS

Putnam Anniversary Volume Anthropological Essays presented to Frederic Ward Putnam in Honor of his Seventieth Birthday, April 16, 1909, by his Friends and Associates New York, G E Stechert & Co 1909

The pupils, colleagues and friends of Professor Frederic Ward Putnam have chosen the very happy and suitable method of celebrating his seventieth birthday by presenting him with a volume of original anthropological essays I had the pleasure of first meeting Professor Putnam at the Toronto meeting of the British Association in 1897 and was at once charmed by his personality Since then I have renewed my friendship with him on every possible occasion, and have been more and more impressed with his enthusiasm and knowledge I have seen the results of his labors in Cambridge, New York and Berkeley and have learned from his pupils how much they are indebted to him for their training, guidance and wise counsel But in addition to gratitude for these advantages they feel a personal affection for the man himself, which is shared also by his colleagues at home, in England and elsewhere It is as an honored and beloved master that his former pupils and friends offer this tribute

It is manifestly impossible to give an account of the twenty-five essays, but the following statement will give some idea of their scope A bibliography of over four hundred items indicates Professor Putnam's activity, but many of these are notes and annual reports It is interesting to find that Professor Putnam, like so many anthropologists, started his scientific life as a zoologist, for ten years he was curator of ornithology in the Essex Institute and later took charge of the Vertebrata Though most of his zoological papers deal with vertebrates, he also published a few papers on invertebrates In 1869 he published the first annual report of the Peabody Academy of Science, and his last purely zoological paper was published in 1879

By far the greater part of Professor Putnam's anthropological work was in the domain of archeology, so it is fitting that the first essay should be on "The Archeology of California," by an old pupil, A L Kroeber; thirty years previously Professor Putnam had written on the subject, and it is well known that the anthropological school of the University of California owes much to his wise direction This essay gives a bird's-eye-view of what has since been accomplished, and enables us to form some estimate of the civilization of the ancient inhabitants of California. Among the archeological papers is a beautifully illustrated memoir on "Ancient Zuñi Pottery," by J Walter Fewkes, which gives a needed synopsis of the old types of decorated vessels of the Zuñi, and the conclusion is drawn that the radical difference in the symbolism of prehistoric and modern Zuñi pottery confirms legendary evidence of the dual composition of the tribe. Charles C. Willoughby describes

[12] *The National Geographic Magazine*, Vol XV, May, 1904, p 221

[13] *Globus*, Vol 86, No 4, p 63

[14] *Petermann's Geographischen Mitteilungen*, 1904, Heft VII, p. 2

[15] *Geographischer Anzeiger*, 1904, IX, p 201.

in an illustrated article the "Pottery of the New England Indians", this falls into three groups, Archaic Algonquian, Later Algonquian and Iroquoian. "The Slip Mound," which is described by William C Mills, belonged to the highest culture of pre-Columbian man in Ohio, the builders of the mound had an intertribal trade, as evidenced by the copper from the Lake Superior region, the ocean shells and alligator teeth from the far south, and mica from North Carolina Mr Warren K Moorehead in his "Study of Primitive Culture in Ohio" establishes Professor Putnam's classification of the remains into the Fort Ancient and Hopewell cultures and adds an earlier one of the "Glacial Kames" The Hopewell culture, to which the Seip Mound belongs, migrated from the south, and the original contention of Professor Putnam that the southern people had short heads and the Fort Ancient people had long heads has been proved Marshall H Saville gives a beautifully illustrated paper on the cruciform structures of Mitla and its vicinity; the form of the cross was connected with the cult of Quetzalcoatl and is proof of the widespread range of the Nahuan pantheon, for we find his worship throughout the area of the Mayan culture, as well as in different parts of Mexico George B Gordon deals with the treatment of the macaw in Mayan art at Copan, and C W Mead with the fish in ancient Peruvian art Mrs Zelia Nuttall shows that the art of dyeing cloth by means of the *Purpura patula* has been continued in Mexico from pre-Columbian times to the present day, and points out that in the old and new world alike these are found in the same close association (1) the purple industry and skill in weaving, (2) the use of pearls and conch-shell trumpets; (3) the mining, working and trafficing in copper, silver and gold, (4) the tetrarchial form of government, (5) the conception of "four elements", (6) the cyclical form of calendar The tribal structure of the Omaha is lucidly described by Miss Alice C Fletcher, and in a well-illustrated memoir A M Tozzer describes several religious ceremonials of the Navaho, who borrowed, to be sure, but they were by no means simply borrowers they adapted and developed and, in many cases, especially in regard to the sand pictures, they did everything but actually invent the idea Papers on linguistics are given by F. Boas (Iroquois), Roland B Dixon (Wintun) and John R Swanton (Siouan) S A Barrett describes the elaborate numerical system of the Cayapa of Ecuador and Charles P. Bowditch discusses some dates and numbers of the Dresden Codex. It is characteristic of the trend of American anthropology that there is only one paper on physical anthropology, that of Aleš Hrdlička, on the stature of the Indians of the southwest and of northern Mexico There are a few papers which deal with non-American subjects, such as Charles Peabody's essay on certain quests and doles, which is a very interesting study on a neglected branch of European folk-lore, and F N Robinson's notes on the Irish practise of fasting as a means of distraint, it being regarded as a procedure which it was in some way dangerous to resist G L. Kittredge in a learned essay brings evidence of a tradition of very long standing which asserts that Hercules set up pillars at both ends of the world, that is at the eastern end as well as the western Professor Putnam, as some of his students have assured me, is a stimulating teacher, which, however, could be readily inferred from the mark his pupils have made in our science, and doubtless he has thoroughly appreciated the development of his ideas in very excellent scheme of instruction in primitive industries suitable for a normal college course by Harlan I Smith.

This brief notice of an important collection of essays may fittingly conclude with an endorsement of the final paragraph of the dedication of the volume to Professor Putnam by Professor Boas

May many years of health and strength be granted you to see the ripening of your plans and the achievements of your younger friends, whose progress has always been a chief pleasure to your life!

Alfred C. Haddon

Blue Hill Meteorological Observatory,

Municipal Chemistry A series of thirty lectures by experts on the applications of the principles of chemistry to the city, delivered at the College of the City of New York, 1910 Edited by CHARLES BASKERVILLE, Ph.D., F.C.S. New York, McGraw-Hill Book Company 1911 Pp 526 $5.00 net

The title of this book is sufficiently suggestive of its intended scope The lectures here brought together in printed form were given before the student body of the College of the City of New York in the spring of 1910 and were open to the public The interest they aroused was taken as sufficient to warrant the publication for a larger audience

Chemistry plays a very important and ever-widening part in the affairs of life, and especially of the life as it is lived in a great city Problems of food supply and preservation, of pure water and disposal of sewage, of garbage cremation and smoke prevention, and a dozen more which might be easily mentioned, call for the aid of the chemist in some direction It is proper to present to young people in college the conception of the chemist as a man who can do things which the city needs, and on a broad scale The chemical problems of the city are not merely those of routine analysis, although many analyses may be necessary in their solution

The men selected by Professor Baskerville to deliver the course of lectures are, for the greater part, well known authorities in their several specialties, and while some of the topics discussed bear but a remote relation to questions of municipal chemistry, in the narrower sense, it must be admitted that they are all of interest at the present time The editor contributes a good introductory lecture The papers by Professor Mason on the relations of drinking water to disease and on the purification of water, by Mr Flinn, of the New York Board of Water Supply, on the water problem in that city and the work in the Catskill Mountains, and by Professor Winslow on the disposal of sewage are perhaps the most interesting in the book The discussion of the city milk supply problem by Dr Darlington is also timely and quite worth reading

In addition to these topics there are lectures on food and drug adulteration, on illuminating gas, smoke prevention, ventilation, explosives, paints, corrosion of metals, cements, road building, textiles, parks and playgrounds It will be seen that a wide range of topics is covered, and in general in a way to interest young people The whole presentation is naturally elementary and not of a character to appeal to specialists In fact, the moderately informed man will recognize most of the discussions as old friends with which he is already familiar But the book is not intended for the well informed but for those who need and are seeking general practical information From this point of view it merits a cordial reception

J. H. LONG

SPECIAL ARTICLES

EXPERIENCES WITH THE GRADING SYSTEM OF THE UNIVERSITY OF MISSOURI[1]

WHY should there be uniformity of grading in an educational institution? somebody might ask If different grades were simply means of giving some students notoriety above others, the question would be immaterial, for a gentleman does not seek notoriety But the grade has in more than one sense a cash value, and if there is no uniformity of grading in an institution, this means directly that values are stolen from some and undeservedly presented to others

The result is that, among the members of the faculty as well as among the students, men look at each other with suspicion That this attitude is detrimental to the feeling of unity, to the development of a college spirit, is clear to even the most superficial observer. Whatever contributes to a greater uniformity of grading, contributes directly towards more peace, a better mutual understanding, a greater community of purpose among all the members of the institution

Whoever admits the fact just stated will find much encouragement in the present

[1] Read before Section L of the American Association for the Advancement of Science at the Minneapolis meeting

status of grading in the University of Missouri, compared with that of three years ago. At that time the university had the traditional marking system based on percentages of an ideal maximum accomplishment, called "100." There would be no objection to this system if all the grading in the institution were done by a single instructor. Experience teaches that different instructors even in the same subject have very different conceptions of what this ideal maximum accomplishment "100" really is.

Among teachers of different subjects this difference of conceiving the maximum accomplishment becomes enormous. There can be then no uniformity of grading, and all the evils resulting from this condition find an open door. Three years ago the diversity of grading had reached such a degree that the faculty took a radical step, abolished the antiquated system and introduced the grading by rank. This does not mean that the teacher is in any way interfered with if he uses, for his private purposes, the marking by percentages of his ideal maximum accomplishment. But the institution no longer accepts such percentages for its official records. Instead the institution requires each teacher to report for each student his estimated rank among a hundred students. This method is a little complex on account of the hundred different grades. To simplify it the grades are united into groups by division lines, which, however, are not at all drawn by each teacher according to his own opinion, but fixed by authority of the faculty of the university. The teacher now divides his list of a hundred students (whom, according to rank, he has graded himself, of course, since no one else can do this) into four groups of twenty-five students each, or, if the teacher prefers, an executive officer of the institution can divide them into these groups.

The students of the first group are marked E or S. Either of these "grades," therefore, does not stand for any degree of accomplishment as defined by anybody, but stands for the numbers from 1 to 25. The faculty has not yet drawn the division line between those of the twenty-five to be marked E and those to be marked S. But the actual practise of two sessions has been to mark the first four E and the following twenty-one S. The following two quarters of the list are marked M. This is prescribed by the rule of the faculty and leaves the teacher no choice. The last twenty-five are again divided into two groups called I and F.

The faculty has again left it, at present, to the discretion of the teacher to draw this division line. But actual practise has shown itself in favor of separating the last seven of these twenty-five as failures, and marking the eighteen students remaining above these seven as I.

Of course, a teacher does not, as a rule, have classes of just a hundred students. But he can distribute the five grades in the same way whatever the actual number of his students. Only in small classes there is this difficulty left that in any semester the membership may be unusually good or unusually bad. The teacher, therefore, is not expected at all to comply with the rule until, possibly after several semesters or even years, he has reported to the official recorder of grades several hundred grades. Then, sooner or later in the case of different individuals, the faculty calls him to account for what he has done. In Missouri the faculty has a special committee charged with this general supervision of the grading.

The system has now been in use for over two years. Considering all the grades reported during these four semesters and three summer sessions, we find that the highest four per cent. are excellent (E), the following twenty-one are superior (S), the following fifty-two are medium (M), the next sixteen are inferior (I) and the last seven have failed (F), not taking into account decimals. The only deviation from the rule, then, consists in this that two of the eighteen students of the I class have been marked one step too high, as M. Such an amount of regularity in general was perhaps to be expected. More interesting is the variation of marking found among the individual teachers.

In order to compare the individual teachers,

let us represent graphically the marking by them of those students who according to the rule ought to be marked M and who are just one half of the total number, having twenty-five per cent above them and twenty-five below. Each of the seventy-two rectangles of the diagram of Fig. 1 represents by its horizontal extent these students. If every teacher

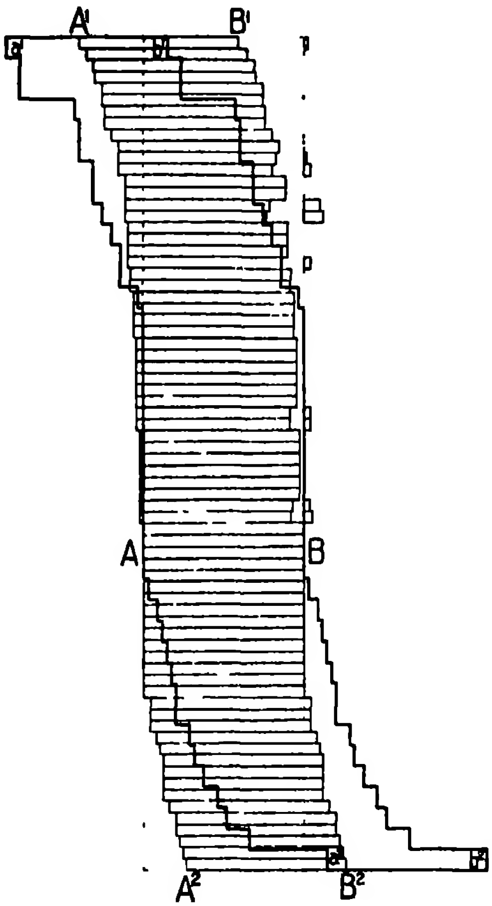

FIG. 1

had actually given all of these students the grade of M, these rectangles would lie exactly one over the other, forming the straight column indicated by the dotted lines. The greater the fraction of these M-students who have received from their teacher S instead of M, the more the particular rectangle reaches beyond the left border of the column. The most extreme case of this high grading is found above at A¹, B¹. Below where the rectangles reach beyond the right border of the column, we find those teachers represented who have given a fraction of their M-students the grade of I. The lack of uniformity may be measured by the ratio of the total area lying outside the column to that of the column itself. This ratio is about ten to a hundred, so that we may say that one tenth of the grades given are unjust in being either one grade too high or one grade too low.

The diagram which has just been explained represents the grading from the time of the introduction of the new system to the end of the first semester of the last session, that is, the grading of three semesters and two summer sessions. The last semester is not included because of a change made in the method of compiling the statistics. The diagram, further, represents only seventy-two teachers. Those who did not report, during the time mentioned, at least ninety grades, have been omitted. It would be unfair to include teachers who had so few students because in the case of these teachers the variations must be regarded as accidental. That the deviation from the standard amounts nevertheless to one tenth illustrates the great resistance with which the introduction of a new system of grading, the requirement of a new way of thinking, meets in a mind influenced by traditions of a different past. There seem to be still not a few teachers who report their E's, S's, etc., as if these grades represented well-defined or definable percentages of a maximum ideal accomplishment of "100" instead of rank. There seem to be others who only with difficulty get accustomed to the idea that we have now four passing grades, whereas formerly we had only three, and who on this account hesitate to assign the fourth grade, the I. However, that these deficiencies in the actual working of the system will speedily disappear seems to follow from the great progress already made, which becomes obvious when we compare the lack of uniformity under the present system of grading with that prevailing under the previous system.

In the same diagram the black lines represent in the same manner the grading by forty teachers of rather large numbers of B-students during five sessions of the university The former passing grades were A, B and C, and these were assigned, on the average, to 24 per cent, 35 per cent and 32 per cent of the students Since the B-group is the largest of these, it is best to use it for comparison with our present M-group The diagram shows what fractions of the B-students were given the grade of A (at the top) or a grade lower than B (at the bottom of the diagram) The scale of drawing, for comparison's sake, has been adjusted so that the central column of this case is identical with the central column for the M-students of the present system The diagram clearly shows that a large fraction of the B-students were formerly unjustly marked other than B, in figures, 24 per cent of them And worse than this, many students were graded two steps lower by one teacher than by another For example, take a student in the center of a file of B-students Under one teacher, at a[1], b[1], in the diagram, such a student standing just in the middle between a[1] and b[1] would invariably receive the grade of A Under another teacher, a student of the same rank of scholarship, standing in the middle between a[2] and b[2], could not entertain the slightest hope of getting a higher grade than C Moreover, the best of the B-students, at the point of a[2] in the diagram, would get no B under this teacher Such enormities of divergence have forever disappeared since the introduction of the new system Even the extreme cases of the M-students, A[1], B[1] and A[2], B[2], overlap to some extent The ratio expressing the lack of uniformity in grading was twenty-four to a hundred as short a time as two years ago It is now ten to a hundred I am confident that it will still further decrease in the near future The improvement already attained is really greater than it appears in the diagram, although it is there conspicuous enough The teachers who varied so enormously under the old system were all teachers of very large classes, so that there was no possible excuse for this variation I must point this out also for another reason Professor Dearborn, in discussing our former variations, thought that they were probably to be explained by the fact that teachers of small and advanced classes had been included in the statistics They were not

I am sure that any institution can in the same way make its grading more and more uniform, but only under the condition that the faculty does not expect mere legislation to accomplish the desired result Our experiences in Missouri prove conclusively that it is absolutely necessary for the faculty to have a special committee which collects each semester the cumulative results of the grading of each teacher and calls attention to those deviations from the rules which seem to be unwarranted We publish each semester among the teachers of the university a statistical table showing how each teacher has thus far graded his students I regard this publicity as essential to the success of our system Besides this, our committee collects data as to the relative standing of special classes of students, for example, athletes, fraternities, women, freshmen, etc

Although the method used by the individual teacher for ranking the members of his class is irrelevant to the system of grading under discussion, I wish to mention briefly the method used by myself because there is no end of complaint on the part of college teachers concerning the large amount of time which the teacher has to spend on examinations I use almost exclusively the conjectural or completion method which was introduced into psychological science by the late Professor Ebbinghaus for the measurement of general intelligence, but can be used with equal success for the measurement of the student's rank in a class The following is an example of an examination blank in which certain words have been omitted The student must fill in the blank spaces in such a manner that the whole becomes meaningful.

The fact of *simultaneous* color induction is well illustrated by the *Hering* window This consists of two narrow windows at some distance from

each other Any object then throws two shadows, one from each window The one shadow coming from the colorless window ought to be simply *dark*, but appears, if the other window contains, say, red glass, of a saturated *red* color because at this shaded spot no *white* light is mixed with the *red* light Everywhere else this mixed illumination takes place and makes the observer overlook the fact that the whole room with everything in it appears actually *reddish* The other shadow, coming from the red window, might be expected to appear simply *white*, since this shaded spot is illuminated only by *white* light As a matter of fact, it appears, by *induction*, *green* because the whole room excepting this spot stimulates on our retina the *red* process The area on the retina corresponding to this shaded spot is therefore the only one where the disturbed *equilibrium* of the components of the *red green* substance can be to some extent *restored* by spontaneous action of the sense organ (Words in italics are blanks)

The maximum number of points which any student could make in the quiz shown is fifteen In case the word inserted was not quite correct, but indicative of the right approach to the solution of the problem, one half point was given A class of twenty-six students made the number of points shown in the table below Students having the same number of points were given precedence according to the order in which they had been able to hand over their quizzes to the instructor Ranking these papers took about thirty minutes, and having completed the task the instructor felt sure that he had done no appreciable injustice to any of the students Ranking twenty-six different essays on the same subject, the Hering window, would have taken several hours, and the instructor would have finished his task with the unpleasant conviction that his ranking in many cases was arbitrary

	Points		Points		Points
1	15	10	12½	19	5½
2	15	11	12½	20	5½
3	14½	12	12	21	5½
4	14½	13	11½	22	5½
5	14	14	10	23	5
6	13½	15	9½	24	4½
7	13	16	7	25	4½
8	13	17	6	26	2½
9	12½	18	6		

I do not record the number of points made in any quiz by any student, but only his rank, placing those who "cut" at the bottom of the class I find that this is an excellent way of insuring class attendance At the end of the semester I sum up the rank numbers of each student and, by the smallness of the total, determine the rank for the whole semester By recording in each quiz, not the points made, but only the rank, we overcome the difficulties in grading caused by the fact that examinations are sometimes too easy, sometimes too hard In either case the best students come out on top, the poor students at the bottom, especially when we take into account, as mentioned above, the time within which each student completed his task

Let us take up another problem, which, it seems to me, is dependent on our system of grading, but which is by no means a part of this or any system of grading I believe that Professor Cattell was the first to point out the justice of giving more credit towards graduation to those students who ranked high in scholarship than to those who ranked low Now, the first and absolute condition of giving varying credit is a method of controlling the uniformity of grading in the institution Without this the injustice done by diversity of grading on the part of different instructors is only multiplied In the University of Missouri we credit an E with 30 per cent plus, an S with 15 per cent plus, an M with the normal credit, an I with 20 per cent minus and an F with nothing It must be understood that the choice of these quantities is for the most part experimental We are gathering data to put our credits on a more strictly scientific basis

I have heard of only one real argument questioning the justice of varying credit Some believe that by letting a student of excellent scholarship graduate after having taken a somewhat smaller variety of courses than the average student, we give the degree to one who does not have the breadth of training which a college graduate ought to

possess. I must say that, judging from my own experience with students, this argument is a fallacious one. I have never had an excellent student in psychology who did not have a good knowledge in languages, in history, in biology, etc. Indeed, I am inclined to assert that his knowledge of these other sciences, his comprehension of the relation existing between psychology and these other sciences, made him an excellent student in psychology. And this, I think, holds good also for other studies, more or less. I therefore believe in varying credit. We ought not to make conditions in college unnecessarily different from conditions in life. In life too our credits vary.

The amount of credit which we give for different scholarly accomplishments depends on our view as to what is the distribution of such accomplishments in a large number of students. The division lines which we draw between the different grades, as explained above, also depend on our assumption of a definite curve of distribution. I am inclined to think that, owing to the insufficient data which we possess at present, we have to base our conclusions on the normal curve. Three years ago I had the honor of speaking on this very question before this section of the American Association. I then criticized certain conclusions drawn by Professor Hall. Since my criticism has been slightly misunderstood, I wish to repeat what I wanted to point out. I did not want to belittle Professor Hall's work on the distribution of scholarly abilities. But I held, and still hold, that Professor Hall found his students distributed in accordance with the normal curve simply because he believed, while he was teaching and examining these students, that they ought to be distributed thus. I shall try to make this clearer.

Fig. 2 shows two entirely different curves of distribution. You may be surprised that these are the same students in the same subject. The only difference is that the broken lines represent the outcome of a very difficult examination, requiring a large amount of reasoning; the continuous lines represent the outcome of an examination of the kind most commonly given by instructors, which enables most of the students to respond to a majority of the points correctly, especially when there

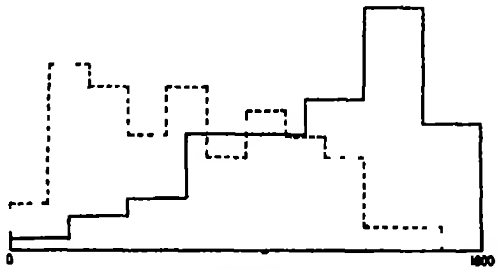

Fig. 2

is no time limit, or when the time of completing the task—of such enormous significance in life—is not taken into account at all. College teachers usually assert that the curve of distribution is not the normal curve, but a skewed curve like that of the continuous lines. They are usually ready to explain this by referring to the elimination of poor scholars in the high schools and lower schools. I have considerable doubts as to this elimination. Is the work done in a high school really so much like that done in college that there is a large previous elimination of poor college students? Our curves clearly show that the skewed distribution which an instructor finds is likely to be simply the result of the kind of examination which he gives. If he believes that the distribution ought to be like the curve of the continuous lines, he will give his examinations accordingly. If he believes otherwise, he will give his examinations otherwise.

I do not admit, then, that anybody has proved thus far that the distribution of scholarly accomplishments in college is like the normal curve or like a curve skewed either way. Under these circumstances, if for any purpose we have to assume, at least provisionally, a particular distribution, I see no other possibility than that of regarding scholarly accomplishments as based on biological properties and assuming the normal curve as the most probable one.

All this, however, does in no way interfere with our actual practise of grading Our division lines between the different grades may be drawn somewhat arbitrarily, the relative credit given for the different grades may be somewhat arbitrary, the injustice done the students under a system which enforces uniformity of grading is nevertheless small compared with the injustice when each instructor is left to grade according to his own fancy

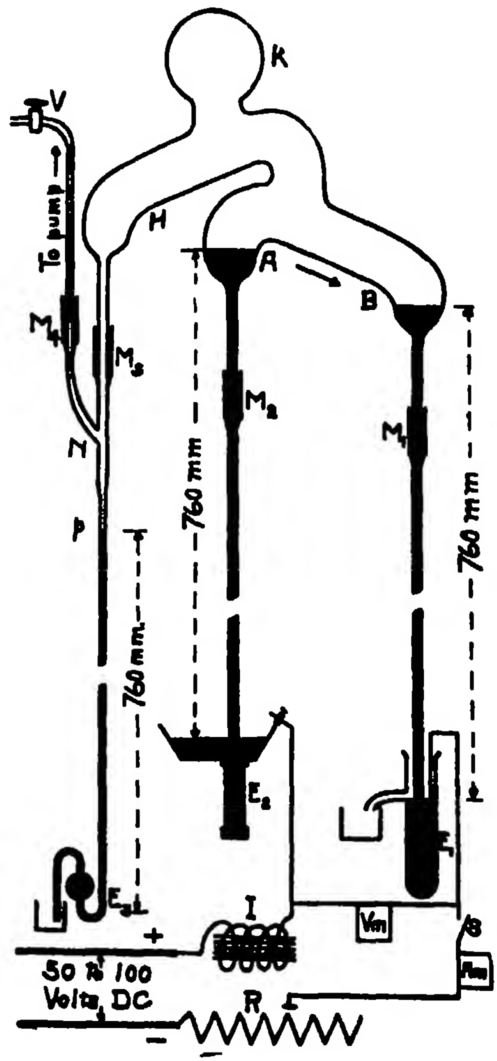
MAX MEYER
UNIVERSITY OF MISSOURI

AN EFFICIENT AND RAPID MERCURY STILL

IT is with some hesitancy that the writer attempts a description of so simple and commonplace an apparatus as a mercury still Nearly every laboratory has its own method of purifying mercury However, of the various "dry" methods that are usually employed two stand out prominently—Weinhold's method and Hulett's method[1] The principle of the first is to distil under reduced pressure or partial vacuum, while the second in addition to this makes use of a small jet of air bubbling up through the mass of mercury The jet of air plays the rôle of oxidizing the metallic impurities Both methods are good The purifying effect of air bubbling through mercury, even at room temperature, is now well recognized

In 1905 the writer described a new form of still,[2] in a brief paper read before the American Association for the Advancement of Science, at its New Orleans meeting, in which use was made of the mercury vapor lamp A description of the apparatus[3] as at present modified and perfected by several years' use in the laboratory is the object of this paper.

It is common observation that mercury condenses on the walls at the cooler parts of the lamp. Now by fusing to the mercury vapor lamp a properly shaped condensing chamber, mercury of a high degree of purity may be obtained. For the apparatus to be a practical working still the lamp must have additional modifications Fig 1 shows all of the essential parts The mercury arc is maintained between the electrodes A and B These electrodes are of mercury and are in communication, through the narrow barometric legs BE_1 and AE_2, with the vessels E_1 and E_2 containing the supply mercury These vessels are connected directly through an adjustable resistance and an inductance to some convenient source of direct current It is well to include



[1] Hulett, *Phys Rev*, Vol XXI, December, 1905
[2] SCIENCE, Vol XXIII, March 16, 1906
[3] Letters Patent, U S A, Nos. 891,264, 891,265; Germany, No 201,017

in the circuit an ammeter, a voltmeter and a switch as shown in the figure

The condensing chamber HK may have a variety of forms—the one sketched possibly serves the purpose best It will be noticed that the condensed mercury is, by the inclination of the tube H, diverted and leaves the still through a capillary delivery tube M_2E_2 bent into the form of an S at its lower end The action of the mercury dropping into this tube is that of a continuous mercury pump The nipple N for initially exhausting the system is fused, for convenience, to the upper end of this delivery tube M_1, M_2, M_3, M_4 are mercury seals

The operation of the still is very simple and when once under way needs but little attention Fill the vessels E_1 and E_2 with the mercury to be distilled and allow the mouth of the delivery tube to dip into a small beaker of clean mercury Now start the exhaust pump (an efficient mechanical pump will answer) and adjust the position of the vessels E_1 and E_2 until the electrodes A and B rise to the heights indicated in the figure The mercury in the delivery tube should now stand at some point p 5 or 6 cm below the nipple N To start the arc it is only necessary to lift the vessel E_1 slightly and allow a momentary stream of mercury to flow down the tube AB If the vacuum is right the arc should start instantly Adjust the current to the proper value After fifteen or twenty minutes the valve V may be closed, provided the various mercury seals do not leak The supply mercury is drawn mostly from the vessel E_2 and it therefore should be of large surface and rather shallow The vessel E_1 is provided with an overflow

The rate of distillation depends upon the size of the apparatus and the strength of current employed In the stills as first constructed the diameter of the tube AB was about 20 mm. This gave for a current of 4 amperes approximately one pound per hour. The corresponding fall of potential across the terminals was 21 volts Later the diameter of AB was increased to 40 mm and its length to 25 cm The size of the condensing chamber HK was proportionately larger This still gave for a current of 10 amperes approximately 2 pounds per hour. The potential difference across the terminals was 23 volts.

To test the purity of the distillate zinc amalgams were used The test for zinc was made by the electromotive-force method described by Hulett One millimeter deflection of the galvanometer corresponded to approximately 0005 volt The results are given in the following table

No	Zinc Amalgam	Distillate from Zinc Amalgam	Deflection of Galvanometer
2a	1 700,000	—	2 17 mm
100	1 370,000	—	4 00 "
a		1 1740	61 "
b		1 1740	19 "
c		1 1740	55 "

From numbers 2a and 100 we see that a deflection of 1 mm corresponded to the presence of zinc in the ratio of 1 1,500,000 Samples a, b, c were from an amalgam that was, comparatively speaking, very impure to zinc, yet the distillates condensed in three separate condensing chambers showed practically no trace of zinc The standard against which the above was balanced in the test cell was newly purchased commercial double distilled mercury and was in addition carefully and repeatedly purified by the "wet" method Numerous additional tests under various conditions have been made and all show that the still is capable of giving a distillate of the highest purity In fact, very pure mercury may be obtained by a single distillation even though the original is very impure As an example may be given a test in which the original mercury was excessively impure to zinc. After distilling off six or eight pounds the current was broken and the apparatus let stand over night. In the morning the anode was completely covered with a layer of zinc an eighth of an inch thick that had crystallized out on cooling The distillate showed scarcely a trace of zinc In this instance the arc was maintained by a small current density and consequently the average temperature[4] in the

[4] Knipp, *Phys Rev*, Vol XXXI, August, 1910

arc was very much below the melting point of zinc

The residue remains within the still This should be digested out from time to time, depending upon the condition of the impure mercury. Where one is dealing with comparatively pure mercury 50 to 75 pounds may be distilled off during a single run

THE ASSOCIATION OF AMERICAN GEOGRAPHERS

THE seventh annual meeting was held at Pittsburgh, December 29–31, 1910, under the presidency of Dr H C Cowles, of the University of Chicago His address was upon the subject, "The Causes of Vegetative Cycles" Public lectures were given by Professor Mark Jefferson on "Rocky Mountain Forms," and by Dr Cowles on the "Origin and Destiny of the Everglades" Professor Rollin D Salisbury conducted a round table conference on the "Purposes of Geographic Instruction, and the Phases of the Subject best adapted to these Purposes" About twenty five papers were read by the members

The following officers were elected *President* Professor Ralph S Tarr, Cornell University, *First Vice president,* Alfred H Brooks, U S Geological Survey, *Second Vice president,* Henry G Bryant, president of the Geographical Society of Philadelphia, *Secretary,* A P Brigham, Colgate University, *Treasurer,* Professor N M Fenneman, University of Cincinnati, *Councillor* (for three years), Professor Herbert E Gregory, Yale University

The following were appointed as delegates to the Geographical Congress to be held in Rome in October, 1911 Cyrus C Adams, A P Brigham, H C Cowles, W M Davis, H W Fairbanks and Ralph S Tarr

Members newly elected are Charles A Davis, U. S Bureau of Mines, F V Emerson, University of Missouri, Otto E Jennings, Carnegie Museum, Pittsburgh, Wolfgang L G Joerg, American Geographical Society, Alexander G Ruthven, University of Michigan, Victor E Shelford, University of Chicago, L H Wood, Western State Normal School, Michigan

The association has voted to establish a publication, and has appointed the following publication committee Richard E Dodge, chairman and editor, Alfred H Brooks, Henry C Cowles and Ralph S Tarr

Following the discussions of the round table conference, the association adopted the resolutions herewith appended

"The Association of American Geographers at its Pittsburgh meeting, December 29–31, discussed the present status of physical geography in secondary education and passed the following resolutions

"*Resolved,* that in the opinion of this association physical geography fully deserves to retain a place in the high school

"That the disappointment or dissatisfaction sometimes expressed regarding the results of teaching this subject is in large measure due to inefficient teaching

"That as a means of removing this dissatisfaction, superintendents and principals are urged to procure teachers of physical geography adequately prepared in their subject, and to entrust the subject only to such teachers

"That no teacher of physical geography should be appointed in any educational grade who has not made serious and special study of the subject in a higher educational grade"

A committee on state educational bulletins was appointed to report at the next meeting N M Fenneman, chairman, W M Davis and R H Whitbeck

The next meeting will be held in Washington in connection with the American Association for the Advancement of Science

ALBERT PERRY BRIGHAM,
Secretary

SOCIETIES AND ACADEMIES

THE FOURTH ANNUAL MEETING OF THE ILLINOIS STATE ACADEMY OF SCIENCE

THE fourth annual meeting of the Illinois State Academy of Science was held Friday and Saturday, February 17 and 18, at the University of Chicago

About two hundred persons attended the combined sessions of the two days, and the excellence of the papers and the general air of enthusiasm which prevailed was on a par, if not in excess, of previous meetings The total membership is now four hundred and eight, of this number, thirty-seven were elected at the Chicago meeting A study of the geographic distribution of the membership is significant, as the annexed table shows

Chicago	118
Urbana	114
Springfield	30
Evanston	12
Decatur	10
Scattered	122

The above condition is a very gratifying result of the four years of the academy's efforts, but it is fully realized that it falls far short of the ideal toward which the state academy is aiming There is no apparent reason why the Illinois State Academy of Science should not, in a few years, have an enrolment of a thousand members and wield an influence for good which will be felt not only by the educational institutions and the citizens of our great commonwealth, but also by our sister states whose state academies preceded ours by several decades

The following officers were elected for the ensuing year

President—W A Noyes, Illinois State University, Urbana, Ills

Vice president—J C Udden, Augustana College, Rock Island, Ills

Secretary—Frank C Baker, The Chicago Academy of Sciences, Chicago

Treasurer—J C Hessler, James Millikin University, Decatur, Ills

The following committees were appointed or continued

Membership Committee—H C Cowles, Chicago, Marion Weller, De Kalb, E N Transeau, Charleston, C C Adams, Urbana, J W Read, Jacksonville

Committee to Investigate the Status of High Schools as to Practical Science—Worrallo Whitney, Otis W Caldwell, J P Gilbert, J C Hessler, J T Johnson

Committee to Arrange for the Editorship and the Publication of a Series to be known as the State Academy Leaflets on High School Science—T J McCormack, William C Bagley, J G Coulter, R D Salisbury, H S Pepoon

Publication Committee—The president, the secretary and A R Crook

Committee on Ecological Survey—Stephen A Forbes, V E Shelford, Frank C Baker, Charles C Adams, H A Gleason

Committee to Influence Legislation to Restrict the Collection of Birds and Eggs to Institutions and Accredited Individuals—F C Baker, I E Hess and F L Charles

Committee to Cooperate with Existing Agencies for Advancement of Nature Study in Elementary Schools—F L Charles, Ira Meyers and Ruth Marshall

The program was as follows (the papers and addresses will be published in Volume IV of the *Transactions*)

FRIDAY, 10 00 A M—*Botany Building*

Address of Welcome, Dean R D Salisbury

"Charles R Barnes In Memoriam," John M Coulter

"Frank G Barnes In Memoriam," R O Graham

"J A West," S A Forbes

"J C Stine In Memoriam," Frank Smith

"The Postglacial Life of Wilmette Bay" (lantern), Frank C Baker

"Description of Mine Rescue Stations" (lantern), H H Stoek

FRIDAY, 2 00 P M—*Botany Building*

"Mollusca of Piatt, Vermilion and Champaign Counties" (lantern), James Zetek

"Oil Investigation in Illinois" (lantern), R S Blatchley

"Seasonal Succession in Old Forest Ponds" (lantern), W C Allee

"Demonstration of Movement of Water in Leaves" (lantern), A H Cole

"The Chinese Mantis in Southern Illinois," C A Hart

"Eastward Extension of Certain Shales as Shown by Deep Wells," J A Udden

"Present Status of Illinois State Museum," A R Crook

"Demonstration of the Use of Oxygen in Mine Rescue Work," J M Webb

"Metallic Colors in Birds and Insects" (lantern), A A Michelson

FRIDAY, 8 00 P M—*Mandel Hall*

Presidential address, "The Problems of Plant Breeding," John M Coulter

SATURDAY, 9 00 A M—*Mandel Hall*

Symposium on Radio Activity "Radio Activity and Geological Phenomena," T C Chamberlin, University of Chicago, "Some of the Physical Properties of Radium," Henry Crew, Northwestern University, "Radium in Relation to Celestial Bodies," E B Frost, Yerkes Observatory, "Radio Chemistry," W A Noyes, University of Illinois, "The Biological Effects of Radium," W A Pusey, University of Illinois

Address "The Relation of the Soil to Plants," H C Cowles

SATURDAY, 2 00 P M —*Botany Building*

"A Preliminary List of the Ants of Illinois," M C Tanquary

"The Channahon and Essex Limestone," T E Savage

"Occurrence of *Glaotanium* in Illinois," E N Transeau

"Ecological Studies of the Prairie and Forest of Illinois," C C Adams

"A Handbook for Students of Animal Ecology," C C Adams

"Reproduction by Layering in the Balsam Fir and other Conifers" (lantern), W S Cooper

"Evaporation and Plant Succession on the Sand Dunes of Lake Michigan" (lantern), George D Fuller

"Structure of Adult Cycad Stem" (lantern), C J Chamberlain

"An American Lepidostrobus" (lantern), John M Coulter and W J G Land

Following the presidential address, a social hour was enjoyed in Hutchinson Hall The social possibilities of the meetings were also taken advantage of during the noon day luncheons served in the men's commons

FRANK C BAKER,
Secretary

THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 182d regular meeting of the society was held March 18, 1911, with President David White in the chair

Under the heading "Brief Notes," C D Marsh called attention to a recent paper on the "Geographic Distribution of Diatomes," by Tollinger, published in *Zoologische Jahrbucher*, Jena The paper is chiefly remarkable for its completeness A separate map of the distribution of each species is given

The following communications were presented

Raising Trailing Arbutus from the Seed FREDERICK V COVILLE

A brief account of scientific phases of the experiments, the results of which were outlined, appears elsewhere in SCIENCE The speaker exhibited a number of pots showing magnificent specimens produced from the seed and grown in the greenhouse

Notes on Java Natural History and Salt Makers of Tjihara, Java WILLIAM PALMER

This was a narrative of experiences and observations made during a somewhat lengthy collecting trip to Java in 1909 and 1910 It included observations on the physical features of the island, the vegetation, the inhabitants, their mode of life and industries, the birds, mammals and other animals The speaker closed with an account of his visit to the salt makers of Tjihara

D E LANTZ,
Recording Secretary

THE BOTANICAL SOCIETY OF WASHINGTON

THE 72d regular meeting was held at the Cosmos Club, Tuesday, April 4, 1911, at eight o'clock P M Both president and vice president being absent, Dr A Mann was chosen chairman *pro tem* Thirty members were in attendance

The following papers were read

The Study of Soil Organisms Dr N A COBB

Notes on some of the Edible Aroids R A YOUNG

The edible aroids are of great importance in the tropics, since they form a readily available source of starch food Practically all desirable varieties must be referred to the genera *Xanthosoma* and *Colocasia*, very few of those belonging to the genus *Alocasia* having any possible use Although the three genera can be distinguished with little difficulty the exact botanical nomenclature of the several varieties, especially those of the genera *Xanthosoma* and *Colocasia*, is in general uncertain

The acrid properties of the aroids, due to the presence of raphides composed of calcium oxalate in their tissues, are very pronounced However, the tubers of many forms are non acrid, and in *C gigantea* Hooker the entire plant is non acrid A peculiarity of the older leaves of this species is the development on the ventral surface of sharply defined, irregular, dark green discs on either side of the midrib

When the corms of the aroids are cooked a violet color develops, the source of which is at present unexplained

Inheritance of Aleurone Color in Corn Hybrids G N COLLINS

This paper reported the behavior of the aleurone color in a series of hybrids between diverse types of maize The aleurone color of corn, while of no practical importance, affords exceptional opportunities for studies of inheritance Being a part of the endosperm the characters of the aleurone cells are subject to xenia, that is, they develop from the union of the second nucleus of the pollen tube and the endosperm nucleus and may be looked upon as belonging to the same generation as the embryo Ordinarily in tracing the behavior of

characters it is necessary to grow hundreds of the hybrid plants or animals in order to secure reliable averages, while with xenia characters similar numbers can be secured by a single pollination and can be observed the same season that the cross is made.

Crosses between white varieties and those possessing a variety of aleurone colors has shown that the law of dominance holds with considerable regularity. Instances of partial dominance occur but are comparatively infrequent. One case was reported in which a blue aleurone color was definitely recessive to white. In the second or perjugate generation segregation, while comparatively definite, seems not to result in the usual ratios. Out of 200 different combinations only 16 approximated the usual ratios of a monohybrid. There was a great variety in the ratios obtained, the most frequent being one colored to two colorless, or 33⅓ per cent. This was approximated within twice the probable error in 22 instances out of 200. It was pointed out that this 1:2 ratio could not be explained by supposing that pure recessive or pure dominants were unable to develop. The regular arrangement of seeds on the ear would render omissions of this kind apparent.

Since the number of seeds on the individual ears was large enough to afford reliable averages, it was held that the differences found were significant, while any attempt to explain the unusual ratios by assuming different combinations of distinct factors for the same character would reduce the whole conception to an absurdity.

W. W. STOCKBERGER,
Corresponding Secretary

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

THE 452d regular meeting of the society was held in the hall of the Public Library, February 21, 1911, 8 P.M., with Mr. George R. Stetson, vice president of the society, in the chair.

Dr. Daniel Folkmar presented a paper on "Some Questions Arising in the First Census of European Races in the United States." The speaker, who is chief of the section on the foreign born in the thirteenth census, and author of the "Dictionary of European and other Immigrant Races," dwelt at some length on the new feature introduced in the present census, namely, of classifying the foreign born by their mother tongue, in addition to that by country or political allegiance. The main part of the discourse was, however, occupied with a defense of the terminology, or nomenclature, adopted in the schedules of the census and in the dictionary, viz., "race" to designate the linguistic divisions of the immigrants, and "nationality" for the country of birth. The speaker admitted that in anthropology and biology the term race is applied to physical traits, but maintained that with the census it was not strictly a scientific question but a practical one, to designate and distinguish given groups of peoples who come to the shores of this country. "Race" seemed to him justified to designate linguistic groups, inasmuch as it points out something essential, which descends by heredity.

The paper as well as the dictionary, which the author laid before the society, were discussed at some length by Drs. Hrdlička, Michelson and Hough, and by Mr. Disserond.

I. M. CASANOWICZ,
Secretary

THE AMERICAN CHEMICAL SOCIETY
NEW YORK SECTION

THE seventh regular meeting of the session of 1910–11 was held at Rumford Hall in conjunction with the American Electrochemical Society, on April 7. Professor Chas. Baskerville presided.

The chairman announced that the section would be deprived of the pleasure of listening to Mrs. Ellen H. Richards at the May meeting by her death, which took place a short time ago, and called upon the secretary, one of her former students, to speak of her life and work. The chairman further announced the death of Mr. B. G. Amend, a former member of the section, and asked Dr. Chas. A. Doremus to say something in this connection. Following Dr. Doremus's remarks, the meeting rose in memory of the two deceased.

The chairman spoke of the work of the Municipal Explosives Commission and called upon Dr. C. F. McKenna to speak on "Suggestions as to Public Safety." The subject was further discussed by Dr. Wm. Jay Schieffelin and Mr. G. W. Thompson.

Professor Wm. H. Walker, president of the American Electrochemical Society, then made his presidential address entitled "Chemical Research and Industrial Progress."

At the conclusion of the address the chairman asked President Walker to preside. Dr. Walker took the chair and called upon Dr. H. E. Patten, of the Bureau of Soils, to present his paper on "The Relation of Surface Tension to Electrochemical Action."

RESEARCH AS A FINANCIAL ASSET[1]

IT is only in our century that there could be much significance to such a title as "Research as a Financial Asset" This is an industrial century, and, whether we are proud of it or not, we are an industrial people For some reasons it may be thought unfortunate that so large a proportion of man's energies should be devoted solely to the industries In some eras we find that there was a predominance of art over industry, in others literature was predominant, in still others war and conquest Once territorial discovery and acquisition predominated, and now, in our own times, the principles of community interest have so greatly developed that we are accustomed to seeing many people who, instead of directly producing their own necessities of life, are more generally producing some one little article which contributes in the lives of others This we recognize as a natural tendency to a higher efficiency Our intricate and delicately balanced system of work is becoming continually more complex, but is certainly still covered by the elemental laws of demand and of survival New discoveries in our day are largely mental, instead of geographical, and the old battles of conquest have become wars with ignorance They are struggles to overcome inefficiencies, attempts to broaden the common mental horizon, as our ancestors broadened their physical horizon Very few people realize the rapidity with which

[1] Presented before the Congress of Technology at the fiftieth anniversary of the granting of the charter of the Massachusetts Institute of Technology

technical advances are being made Few realize how the way of this advance has itself advanced I might make this more clear by an illustration

Consider for a moment the increasing uses of chemical elements and compounds New combinations in alloys, medicines, dyes, foods, etc, and new uses and new materials, are being produced daily For a more simple comparison, consider only the advances in our technical uses of the metallic chemical elements

Copper, iron and five other metals were known and used at the time of Christ In the first 1,800 or 1,900 years of our era, there were added to the list of metals in technical use (pure or alloyed) about eight more, or a rate below three a century There has been so much industrial advance made within the past twenty to thirty years that fourteen new metals have been brought into commercial use within this period This is almost as many in our quarter century as in the total preceding age of the world Of course this rate, as applied to metals, apparently can not continue, but there is no reason to question the possibility of the general advance it indicates For centuries a single metal was made to serve for all uses which that metal could fill Then two metals divided the field, each being used where it was preferred for any reason Alloys began to displace metals to a limited extent While the engineer still uses iron for his railroad, iron for his buildings and iron for his tools, these irons are different and have been specially developed for those uses The electrical engineer prefers copper for his conductor, certain irons for the frames of apparatus, other special irons and steels for the shafts, the magnetic fields, etc, and the specialization to best meet specific wants is still under way I suppose that this kind of complex development is largely responsible for research laboratories

A research laboratory is a place where men are especially occupied with new problems, presumably not too far in advance of technical application. By this group devoting its entire attention to the difficulties of realizing already well defined necessities, or of newly defining and realizing together, the efficiency of these processes is increased Men specially trained for this very purpose are employed and they are usually just as unfitted for successfully manufacturing as those who efficiently reproduce are of discovering or inventing It is merely an extension of the principle of the maximum efficiency A man with his entire attention devoted for months or years at a time to the difficulties of a single problem should be better able to reach a solution than the man who can devote only irregular intervals to it He should then also be the better prepared for a second problem

A research laboratory is also a place equipped with apparatus especially designed for experimental work In a busy manufacturing plant, if a foreman has an idea pointing towards an improvement of his product he frequently has great difficulty in finding the time, the necessary idle apparatus, the raw materials and the incentive to try it In the laboratory all of these are combined and there is added a system of cooperation, of permanently recording results and an atmosphere of research

The mathematics of cooperation of men and tools is interesting in this connection Separated men trying their individual experiments contribute in proportion to their numbers, and their work may be called mathematically additive The effect of a single piece of apparatus given to one man is also additive only, but when a group of men are cooperating, as distinct from

merely operating, their work rises with some higher power of the number than the first power. It approaches the square for two men and the cube for three. Two men coöperating with two different and special pieces of apparatus, say a special furnace and a pyrometer, or an hydraulic press and new chemical substances, are more powerful than their arithmetical sum. These facts doubtless assist as assets of a research laboratory.

When a central organization, such as a laboratory, has access to all parts of a large manufacturing plant and is forced sooner or later to come into contact with the various processes and problems, the various possibilities and appliances, it can hardly fail to apply, in some degree, the above law of powers.

As a possible means of illustrating the almost certain assistance which one part of a manufacturing plant may give another when they are connected by experimenting departments or research laboratories, and how one thread of work starts another, I will briefly review part of a single fairly connected line of work in our laboratory. In 1901 the meter department wanted electrically conducting rods of a million ohms resistance. These were to be one quarter inch diameter by one inch length. In connection with this work we had to become fairly familiar with published attempts at making any type of such high resistances. Some kind of porcelain body containing a very little conducting material seemed a fair starting formula after the resistance of almost all kinds of materials had been considered. Our own porcelain department was of a great help in showing us how to get a good start. We learned how and what to mix to get a fair porcelain, and we found that small quantities of carborundum or of graphite would give us the desired resistance about once in a hundred trials. The rods could be made, but the variation of their resistance when taken from the porcelain kiln and when they were made as nearly alike as we could make them, was often so many thousand fold that something now had to be done to make a practical success. A small electric furnace was then devised for baking the rods and this was so arranged that the rate of rise of temperature, the maximum temperature reached and the duration of heat at any temperature was under control and was also recorded. The desired result was obtained and this work was thus finished. It gave us a certain stock of knowledge and assurance.

At that time a very similar problem was bothering one of the engineering departments. Lightning arrester rods, part of the apparatus for protecting power lines from lightning, were needed. Their dimensions were $\frac{3}{4} \times 6$ inches and they needed to have a definite but, in this case, *low* resistance, and could apparently not be baked in a porcelain kiln. The necessary variations in such a kiln are so great that in practise many thousand rods were repeatedly fired and afterward tested to yield a few hundred of satisfactory product. All the cost of making an entire batch would have to be charged against the few units which might be found satisfactory, and in many cases there were none good in a thousand tested. It was evident that regulation and control of temperature was necessary. This was found to be impracticable in case any considerable number were to be fired at one time, as the heated mass was so great that the rods near the walls of the retort received a very different heat treatment from those near the middle and were consequently electrically different. This was still the case even when electrically heated muffles were used. This difficulty led to experiments along the

line of a heated pipe, through which the rods could be automatically passed. Some time was spent in trying to make a practical furnace out of a length of ordinary iron pipe, which was so arranged as to carry enough electric current to be heated to the proper baking temperature. Troubles here with oxidation of the iron finally led to substitution of carbon pipes. This resulted in a carbon tube furnace, which is merely a collection of six-foot carbon pipes, embedded in coke powder to prevent combustion, and held at the ends in water cooled copper clamps, which introduce the electric current. By control of this current the temperature could be kept constant at any point desired. When this was combined with a constant rate of mechanical feed of the air dried rods of porcelain mixture, a good product was obtained. For the past seven years this furnace has turned out all the arrester rods, the number produced the last year being over 100,000 units.

In this work we were also forced to get into close touch with the electroplating department. The rods had to be copper plated at the ends, to insure good electrical contact. The simple plating was not enough. This introduced other problems, which I will pass over, as I wish to follow the line of continuous experiment brought about, in part, at least, by a single investigation. The electric furnace consisting of the carbon tube packed in coke was a good tool for other work, and among other things we heated the carbon filaments for incandescent lamps in it. We were actuated by a theory that the high temperature thus obtainable would benefit the filament by removal of ash ingredients, which we knew the ordinary firing methods left there. While these were removed, the results did not prove the correctness of the theory, but rather the usefulness of trying experiments. It was found by experiment that the graphite coat on the ordinary lamp filament was so completely changed as to permit of a hundred per cent. increase in the lamp life or of a 20 per cent. increase in the efficiency of the lamp for the same life, so that for the past four or five years a large part of the carbon lamps made in this country have been of this improved type. This is the metallized, or Gem lamp. Naturally, this work started a great deal of other work along the lines of incandescent lamp improvement. At no time has such work been stopped, but in addition to it, the new lines of metallic filament lamps were taken up. In fact, during the past five or six years, a very large proportion of our entire work has been done along the line of metallic tungsten incandescent lamps. In this way we have been able to keep in the van of this line of manufacture. The carbon tube furnace has been elaborated for other purposes, so as to cover the action under high pressures and in vacuo. Particularly in the latter case a great deal of experimental work has been carried out, contributing to work such as that connected with rare metals. In such a furnace, materials which would react with gases have been studied to advantage. Our experience with the metallized graphite led to production of a special carbon for contact surfaces in railway signal devices, where ordinary carbon was inferior, and suggested the possibility of our contributing to improvements in carbon motor generator brushes. On the basis of our previous experience and by using the usual factory methods, we became acquainted with the difficulties in producing carbon and graphite motor brushes with the reliability and regularity demanded by the motor art. Furnace firing was a prime difficulty. Here again we resorted to special electrically heated muffles,

where the temperatures, even below redness, could be carefully controlled and automatically recorded. This care, aided by much experimentation along the line of composition, of proportionality between the several kinds of carbon in the brush, etc., put us into shape to make really superior brushes. The company has now been manufacturing these for a couple of years, with especial reference to particularly severe requirements, such as railway motors. In such cases the question of selling price is so secondary that we can and do charge liberally for delicacy and care of operation in the manufacture.

This carbon work naturally led to other applications of the identical processes or materials. Circuit breakers, for example, are now equipped with a specially hard carbon contact, made somewhat as motor brushes are made.

It is not my intention to connect all of the laboratory work to the thread which seemed to connect these particular pieces of work, but rather to show the possible effect in accumulating in a laboratory, experiences which should show on an inventory.

Among other considerations which appeal to me is one which may be worth pointing out. Probably almost every manufacturing plant develops among its workmen from time to time, men who are particularly endowed with aptitude for research in their line. They are usually the inventors of the company. They are often discovered in spite of opposition. They are always trying new things. They are almost of necessity somewhat inefficient in the routine production. In many plants they are merely endured, in a few they are encouraged. In my mind their proper utilization is a safe investment. A research laboratory assists in such a scheme. Sooner or later such a laboratory becomes acquainted with this type of men in a plant and helps them in the development of their ideas.

It is not a perfectly simple matter to measure the value of a research laboratory at any one time. In the minds of some, the proper estimate is based on the money already earned through its work, which otherwise would not have been earned by the company. This is a fair and conservative method which in our generation ought to be satisfactory when applied not too early to the laboratories. It does not take into account what we may call the good-will and inventory value, both of which should be more rapidly augmenting than any other part of a plant. The experience and knowledge accumulated in a general research laboratory is a positive quantity. In our own case we expended in the first year not far from \$10,000, and had little more than expectations to show for it. Our expenses rapidly rose and our tangible assets began to accrue. Perhaps I can point to no better criterion of the value of a research laboratory to our company than the fact that its force was rapidly increased by a company which can not be particularly interested in purely academic work. Our annual expenditures passed the \$100,000 mark several years ago. My own estimate of the value would probably be greater than that of others, for I am firmly convinced that proper scientific research is demanded by the existing conditions of our technical age.

Without going into exact values, which are always difficult to determine, consider for a moment the changes which incandescent lighting has witnessed in the past ten years. In this field our laboratory has been active, in contributing to both carbon and to metallic filaments. Moreover, all of the improvements in this field have been the product of research laboratories of trained

men In the case of our metallized carbon filament, which has now been in use several years, the efficiency of the light was increased by about twenty per cent Among the carbon lamps of last year these were sold to the extent of over a million dollars

A broader, but perhaps less accurate impression of changes recently produced, may be gained by considering the economy now possible on the basis of our present incandescent lamp purchases in this country and that which would have resulted if the lamps of only ten years ago were used in their stead On the assumption that the present rate of lamp consumption is equivalent to about eighty million 25 watt tungsten lamps per year, and on the basis of one and a quarter watts per candle power as against 3 1 of the earlier lamps and charging power at 10 cents per kilowatt hour, we get as a result a saving of $240,000,000 per year, or two thirds of a million per day Naturally, this is a saving which is to be distributed among producers, consumers and others, but illustrates very well the possibilities It is interesting to note that we are still very far removed from a perfect incandescent illuminant, when considered from the point of view of maximum theoretical light efficiency

I see from advertisements that 65,000 of the magnetite arc lamps, originally a product of the laboratory, are now in use These must have been sold for something near $2,000,000 The supplying of electrodes, which we make and which are consumed in these lamps, should amount to about $60,000 per year

Our study of the properties of the mercury arc produced our rectifier, which has been commercially developed within the past few years Of these, about 6,000 have been sold As they sell for not far from $200 per set, it is safe to say that this also represents a sale of over a million dollars The advantage of these outfits over other available apparatus must also be recognized as not far from $200 for each hour through which those already sold are all operating

In such a complex field as insulations and molded materials there have been many changes produced As far back as 1906 we were using annually, in a certain apparatus, 30,000 specially drilled and machined soapstone plates, which cost $1 10 each As the result of experiments on substitutes for such material, it was found that they could be molded by us in the proper shape, with holes in place and of a material giving increased toughness, at a greatly reduced cost As the result of this fact, the price of the purchased material was reduced to us from $1 10 to 60 cents which in itself would have paid for the work But further developments proved that the new molded material could be made for 30 cents, which the foreign material could not equal, so we have since produced it ourselves This caused a saving of approximately $24,000 annually for this one molded piece I have heard of other cases where prices to us have gone down, when we have obtained a little promise from our experimental researches

In considering the research laboratory as a financial asset there is another view which might not be visible at first sight It is the question of the difference between the value of the useful discovery when purchased from competitors in the business and when made by one's own company It is not usually pleasant to have to purchase inventions after their value is known, no matter from whom, but to have to pay a competitor for such a discovery is doubly irksome One is naturally unduly fearful of its value to the competitor, and he, in turn, is overestimating another's power to use it The purchaser's profit is

apparently limited to the differences between his efficiency of operating it and that of the original owner A business usually comprises processes of making and selling something at a profit, and study of the making of the most modern, most improved, most efficient, is about as essential as the study of the limits of safe business credits

I was recently informed by an officer of another large manufacturing company, where much chemical work is done and which established a research laboratory several years ago, that the most important values they got from their laboratory was the assurance that they were keeping ahead and are at least prepared for the new, if they can not always invent it themselves Incidentally, he said that from one part of their research work they had produced processes, etc, which had saved $800,000 a year They are at present spending in their several research departments a total of about $300,000 a year

We hear frequent reference to the German research laboratories and a brief discussion may be in place For the past fifty years that country has been advancing industrially beyond other countries Not by newly opened territories, new railroads, new farm lands, new water power cities, but by new technical discoveries In fact, this advance may be said to be largely traceable to their *apparent* over-production of research men by well fitted universities and technical schools Every year a few hundred new doctors of science and philosophy were thrown on the market Most of them had been well trained to think and to experiment, to work hard, and to expect little The chemical manufactories began to be filled with this product and it overflowed into every other calling in Germany These well educated young men became the docents, the assistants and the professors of all the schools of the country They worked for $300 to $500 per year They were satisfied so long as they could experiment and study the laws of nature, because of the interest in these laws instilled into them by splendid teachers This condition soon began to make itself manifest in the new-making of things--all sorts of chemical compounds, all kinds of physical and electrical devices I might say that pure organic chemistry at this time was academically most interesting Its laws were entrancing to the enthusiastic chemist and consequently very many more doctors were turned out who wrote organic theses than any other kind What more natural than that organic chemistry should have been the first to feel the stimulus? Hundreds, and even thousands of new commercial organic products are to be credited to these men and to that time All the modern dye stuffs are in this class Did Germany alone possess the raw material for this line? No! England and America had as much of that But Germany had the *prepared men* and made the start

It seems to me that America has made a start in preparing men for the research work of its industries For example, it is no longer necessary to go abroad to get the particular training in physical chemistry and electro-chemistry which a few years ago was considered desirable Advanced teaching of science is little, if any more advanced in Germany to-day than it is in this country In my opinion the quality of our research laboratories will improve as the supply of home trained men increases, and the laboratories of this kind will be increasingly valuable when analyzed as financial assets I am certain, too, that the industries will not be slow in recognizing the growing value of such assets They merely want to be shown

Probably in most industries there are

what I may call spots particularly vulnerable to research For example, the efficiency of steam boilers, based upon the heat energy of the coal used and the efficiency of the engine using the steam, are continually being raised We may expect, until the maximum calculable efficiency is reached, that this advance will continue The reason is not far to seek It is a vulnerable spot Improvement is possible A small increase in efficiency of a power plant is an ever-continuing profit Great numbers of steam power plants exist and so inventors are influenced by the fact that new improvements may result in enormous total economies Every rule of the game encourages them I can make this clearer by illustrations

Artificial light is still produced at frightfully poor efficiency Electric light from incandescent lamps has been greatly improved in this respect, but there is still room for greater economies It is still a vulnerable spot

In the case of iron used in transformers, we have another such vulnerable spot A transformer is practically a mass of sheet iron, wound about with copper wire The current must be carried around the iron a certain number of times and the copper is chosen because it does the work most economically No more suitable material than copper seems immediately probable, nor is there any very promising way of increasing its efficiency, but in the iron about which it is wound there is a vulnerable spot The size of the iron about which the copper is wound may possibly be still much further reducible by improvements in its quality In other words, we do not yet know what determines the magnetic permeability or the hysteresis of the iron, and yet we do know that it has been greatly improved in the past few years and that it can still be greatly improved

Let us make this vulnerable point a little clearer by considering the conditions here in Boston I assume there are approximately 50,000 kw of alternating current energy used here Nearly all of this is subject to the losses of transformers If the transformers used with this system were made more than ten years ago, they probably involve a total loss, due to eddy and hysteresis, of about $1,000 per day, at the ten-cent rate Transformers as they are made to-day, by using improved iron, are saving nearly half of this loss, but there still remains over $500 loss per day, to serve as a subject for interesting research work

It should also be noted that Boston uses only a very small fraction of the alternating current energy of this country

Consider for a moment two references to the sciences and industry in Germany and England Dr O N Witt, professor in the Berlin Royal Technical High School, reporting to the German government in 1903, says "What appears to me to be of far greater importance to the German chemical industry than its predominant appearance at the Columbian World's Fair, is the fact which finds expression in the German exhibits alone, that industry and science stand on the footing of mutual deepest appreciation, one ever influencing the other," etc As against this, Professor H E Armstrong, of entirely corresponding prominence and position in England, says of England "Our policy is the precise reverse of that followed in Germany Our manufacturers generally do not know what the word research means They place their business under the control of practical men , who, as a rule, actually resent the introduction into the work of the scientifically trained assistants " If the English nation is to do even its fair share of the work of the world in the future, its attitude

must be entirely changed It must realize that steam and electricity have brought about a complete revolution, that the application of scientific principles and methods is becoming so universal elsewhere that all here who wish to succeed must adopt them.

So long as motors burn out, so long as subways are tied up by defective apparatus, so long as electric motors run too hot, so long as street cars can catch fire from so-called explosions of the current, so long as the traffic of a whole city can be stopped by a defective insulation or a ten cent motor brush, there will probably be the equivalent of research laboratories somewhere connected with the electrical industries, where attempts will be continually made to improve

WILLIS R WHITNEY
GENERAL ELECTRIC COMPANY,
SCHENECTADY, N Y

RECLAMATION OF THE ARID WEST[1]

THE benefits derived by applying science to industry and the still greater benefits that may be expected when all great problems are attacked in the scientific spirit and on the scientific methods are to a certain extent exemplified by the opportunities afforded and results now accomplished in the conservation of the natural resources of the nation

The reclamation of the arid west is simply one of a number of items of national importance upon whose correct solution by true scientific methods rests largely, not merely the material prosperity of the nation, but, more than this, the perpetuation of free government, and of high standards of individual liberty

The stability of a republic or democracy, whichever we may term it, rests not upon its wealth, but upon the character of the individual citizen and voter. The greatest commonwealths are not necessarily those having the greatest natural resources, but rather those in which the human units are strong The strength of the unit, the family or the voter, is not derived from material wealth, but from ability to act and think independently and to exercise that intelligent self-interest which binds him to the great mass of his fellow men If, for example, he is working in a factory or on a railroad line, he is, of course, interested in keeping his job Beyond this, he has little concern with the condition of municipal, state or federal affairs These are entirely too remote to touch him, and if he lives in a tenement, he has no concern beyond paying his rent and getting the most he can for it

But take this man, indifferent to forms or details of government, and put him upon a 40-acre farm Assuming that he has reasonable industry and intelligence, his whole view-point of life changes He is transformed from being more or less of a nomad, shifting from flat to flat, or from town to town, and indifferent to the general welfare He now becomes a land-owning citizen and voter, interested in every public movement for better roads, better schools, better local government and everything which leads up to the stability of the institutions of the state as upon these rest the value and comfort of his home

This thought has been most pithily embodied in a statement attributed to Edward Everett Hale where he asks "Whoever heard of a man shouldering his musket to fight for his boarding house?"

The problem of the reclamation of the arid west is being attacked primarily for the purpose, not of making men rich, but

[1] Presented before the Congress of Technology at the fiftieth anniversary of the granting of the charter of the Massachusetts Institute of Technology

of strengthening the foundations of the state. It is an attempt being made by the federal government almost at the eleventh hour of its opportunities to utilize the waste resources still remaining at its command, and to employ these in such a way as to strengthen local communities and states, and to create in the more remote parts of the country many prosperous communities composed of independent, landowning citizens, each family being resident upon a farm sufficient for its support, and cultivating the soil intensively, under favorable conditions of sunlight and of water supply, such as to produce the largest crop yield per acre, and to bring about the largest individual success.

The people thus placed upon the farms are not merely producers. They not only raise enough to support themselves, and to sell to their neighbors, but indirectly they stimulate all industries. They are large consumers, as well as producers, and it may be said that for every family placed upon an irrigated farm on the desert, there arises the possibility of another family engaged in transportation or in manufacturing in the east or middle west. All parts of the country are thus linked together. The success of the irrigator in the west means larger cotton production in the south, more boots made in Massachusetts, more freight and passenger cars hauled across the continent.

The success already attained in applying scientific methods to this great problem of conservation of the waste resources of the country may be attributable in part at least to the Institute of Technology, and to the instruction there given. The Reclamation Service, organized under the act of June 17, 1902, includes among its principal men and guiding hands many graduates or students of the Institute of Technology.

The training at the institute has been peculiarly effective in building up in the minds of its students a grasp of the larger conditions, and a proper confidence in ability to handle these. The first thing in any undertaking, such as that of studying the resources of a nation, is to gain a comprehensive view of these and to set on foot investigations and measurements in detail such that the conclusions will have direct value and application to the larger problems involved.

With a comprehensive and reasonably accurate review of the conditions to be met, it is then possible to bring to the solution of the problem the principles and methods of engineering and to put into play the constructive ideas which are inseparable from a technologic education.

The great difference between the methods pursued at the institute and those at many of the older institutions appears to lie in this constructive idea in the inculcation of the conception that the great work of life is to initiate and to build on correct lines rather than to simply know what others have done, and to imitate those.

The constructive faculty, the ability to imagine or to picture desirable results, and to turn these into accomplishment by scientific methods is the foundation for success in these larger lines of work.

In the matter under consideration congress in 1888 authorized an investigation of the extent to which the arid lands might be reclaimed. This problem is enormous and its correct solution is fundamental to the future growth and development of the nation, because of the fact that one third of its area is arid. In that third are potentially some of the most valuable lands in the world.

The problem is to obtain water for these lands. This in turn rests upon questions of economics and engineering, in storage

of flood or other waste waters, and in the adjustment of a form of agriculture suited to these conditions The results already attained show that the lands are not only capable of supporting a large population, but under government auspices many thousands of families have been settled in prosperous homes and a highly desirable class of citizenship has been created in a most sparsely populated part of the country

As a natural outgrowth of the investigation begun in 1888, the so-called Reclamation Act of June 17, 1902, was passed, setting aside the proceeds from the disposal of public lands for the construction of works for the reclamation by irrigation of the arid and semi-arid lands It has been held that congress has absolute control over the public lands and of the funds arising from their disposal, and while it might be questionable as to whether the United States could levy taxes, and thus raise money for reclamation, it has been considered that congress could properly create a trust fund derived from the source named This fund has amounted to over $60,000,000, and is being added to at the rate of six or seven millions a year It has been invested in the construction of reservoirs, canals and distributing systems, and already twenty-seven projects have been initiated or completed, works having been undertaken in each of the western states and territories

Over a million acres have been reclaimed, and 14,000 families are receiving water from works built or controlled by the government, under the terms of this act Reservoirs have been built having a capacity of nearly 5,000,000 acre-feet, that is to say, the water would cover 5,000,000 acres to a depth of one foot Canals of large size, carrying over 800 cubic feet per second, have been built for a total length of 300 miles, and somewhat smaller canals constructed with a length of a thousand miles including the ditches There are over 5,000 miles of water courses, also nearly 70 tunnels with a total length of about 20 miles The smaller structures number over 20,000 including bridges, culverts, headgates, siphons, etc Nearly 60,000,000 cubic yards of earth have been excavated and 10,000,000 of loose and solid rock

The principal results, however, are shown in the crop production and although the works are hardly built to a point further than to try out productions it appears that the value of the crops raised in 1910 was nearly $20,000,000 Land values have advanced from practically nothing to one hundred million dollars These values will continue to increase as the works near completion

The object, however, as before stated, is not to make men rich, but to make homes for citizens who will preserve the institutions of the country, and to do this without imposing a burden upon the taxpayers It has been shown how this is being accomplished by the use of the reclamation fund, which is revolving and growing larger and larger, that is to say, as the money comes back from the works completed, it is used over again and is being increased by additions from the disposal of other public lands Under wise administration the funds should increase and produce larger and larger results in the conservation of the waste waters and the utilization of these in those parts of the United States where rain is infrequent and where the brilliant sunshine can be depended upon nearly every day in the year It is really the sunlight which is capitalized and made valuable

The question is frequently asked, why should not the government reclaim the

worthless lands in the east? The answer lies largely in the fact that no other part of the country than the arid west has such wonderful opportunities for crop production, as it does not have the continuous daily sunshine upon which plant life depends The advantages of the development in the arid region also are greater from the political standpoint, as population is better distributed and is brought nearer to important sources of mineral wealth, enabling development of industries in otherwise remote and inaccessible localities

All of these results are successful in proportion as they have been brought about by scientific methods, and by following the principles inculcated at the schools of which the Institute of Technology is chief

F H NEWELL

U S RECLAMATION SERVICE,
WASHINGTON, D C

THE ST LOUIS UNIVERSITY EXPEDITION TO COLORADO

IN a recent number of the *Fleur-de Lis*, one of the publications of the St Louis University, there appears an article on a geological expedition to Colorado, organized last summer by that university Its purpose was to afford an opportunity of geologic field-work to those teachers who were called upon to teach geology as an accessory subject, in addition to other regular work Accordingly, those who availed themselves of the opportunity were chiefly professors of physics and chemistry They were Professor John P. Coony, head of the department of chemistry, St Louis University Medical School, James I Shannon and Charles Cloud, professor and associate professor, respectively, of physics, and Theodore Schulte, professor of chemistry, St Louis University, Joseph Wilczewski and William Agnew, of the department of physics, St. Ignatius College, Chicago, A M Schwitalla, professor of chemistry, St Xavier College, Cincinnati, Vincent Jenneman, professor of physics, Sacred Heart College, Prairie du Chien, Wis ; Hugo Sloctemeyer, curator of the Mineralogical Museum, St John's University, Toledo, O

Colorado, and especially the foot-hill region, was chosen for its variety of geological formations within a comparatively small area Ten days were spent near Cañon City chiefly to study the occurrence and formation of igneous and metamorphic rock in the Royal Gorge of the Arkansas River Camp was then moved to Garden Park, ten miles north, where during four days attention was principally directed to the foot-hill topography and the strata profiles in Oil Creek Cañon The famous dinosaur beds of the region were also examined as carefully as was possible under the circumstances Finally, more than two weeks were spent in the Ute Pass near Manitou, where, besides special problems investigated by the individual members of the party, some coordinated work was done on the formations of the Manitou embayment, and the Archæan-Cambrian contact in this region The pedagogical character of the work was continually kept in mind, and the results were such as to warrant a repetition of the experiment

A M SCHWITALLA

RESOLUTIONS ON THE DEATH OF PROFESSOR CHARLES OTIS WHITMAN

AT the Ithaca meeting of the Eastern Branch of the American Society of Zoologists in December, 1910, it was voted that "the president appoint a committee to prepare a resolution on the death of Professor Whitman, the resolution to be published in the minutes of the society, and transmitted to the family of Professor Whitman" In accordance with this vote Professor S F Clarke and Professor F R Lillie were appointed on this committee They have prepared the following resolutions which have been incorporated in the permanent records of the society

The Eastern Branch of the American Society of Zoologists records with profound regret the death of Professor Charles Otis Whitman on December 6, 1910 Professor Whitman was one of the founders of this society, he was chairman

of the committee that issued the first call for organization of the American Morphological Society, the forerunner of the American Society of Zoologists, and he was president of the society for the first four years, 1891-94. He was organizer of the *Journal of Morphology* and its editor for many years, and in this capacity also exerted a strong influence on the development of zoological research in America. As director of the Marine Biological Laboratory for twenty-one years, he exerted an even more powerful and entirely unique influence in the development of biological science. As an investigator he was painstaking, enthusiastic and thorough, as a thinker on biological problems profound and far sighted. Devoted to principle, his uncompromising personality sometimes made enemies, but the charm of his character made him devoted friends. His influence will long remain as one of the most important forces in the history of zoology in America.

SCIENTIFIC NOTES AND NEWS

JOHN WILLIAM DRAPER, eminent for his contributions to physics, chemistry and physiology, was born on May 5, 1811, and the centenary of his birth is being celebrated by New York University, where he was professor from 1839 until 1873.

THE Paris Academy of Sciences has elected as corresponding members Professor Svante Arrhenius, of Stockholm, in the section for physics, and Professor I. P. Pawlow, of St. Petersburg, in the section of medicine.

AS already announced, the British Association will meet at Portsmouth on August 30. On the evening of that day, Sir William Ramsay will give the presidential address. Public lectures will be given by Mr. Leonard Hill on the "Physiology of Submarine Work," and by Professor A. C. Seward on "Links with the Past in the Plant World."

THE Association of German Men of Science and Physicians will hold its eighty-third meeting at Karlsruhe from September 24 to 30.

MR. J. H. GRISDALE has been appointed director of the experimental farm system of Canada, to succeed Dr. William Saunders.

PROFESSOR LOUIS DOREMUS HUNTOON, M.E., of the department of mining and metallurgy, Sheffield Scientific School, Yale University, has resigned his position to engage in work in the Canadian gold fields.

DR. F. W. WOLL, professor of agricultural chemistry in the University of Wisconsin, has been designated as the delegate of the university at the celebration of the centennial of the University of Christiania, Norway, September 2 to 6, 1911. Dr. Woll is a graduate of the University of Christiania.

PRESIDENT TAFT has appointed the following as the official representatives of the respective bureaus of the federal government on the organizing committee of the International Congress of Applied Chemistry: *Department of the Treasury*—Dr. Reid Hunt, Hygienic Laboratory, Marine Hospital Service; Dr. A. B. Adams, Internal Revenue Service. *Department of the Interior*—Mr. George Seiger, Geological Survey; Dr. George S. Ely, Patent Office; Professor Nathaniel W. Lord, Ohio State University, Columbus, O., to represent Bureau of Mines. *Department of Agriculture*—Dr. H. W. Wiley, Chief, Bureau of Chemistry; Dr. C. F. Langworthy, Office of Experiment Stations; Professor W. W. Cooke, Biological Survey; Mr. William L. Hall, Forest Service; Dr. Frank E. Cameron, Bureau of Soils; Professor W. J. Humphreys, Weather Bureau; Dr. R. H. True, Bureau of Plant Industry; Dr. Marion Dorset, Bureau of Animal Industry; Dr. W. F. Hillebrand, Chief Chemist, Bureau of Standards.

PROFESSOR K. L. HATCH, of the University of Wisconsin, has been elected president of the newly founded American Association for the Advancement of Agricultural Teaching in Secondary Schools, which was launched in Chicago at a meeting of all the heads of departments of agricultural education in the universities and colleges in the north central states. Representatives from the United States Department of Agriculture were also present. The purpose of the new society is to organize and systematize agricultural material so that it can be used with greater efficiency in propagating agricultural education through the medium of the high schools of the nation.

MR K F KELLERMAN, physiologist in the Bureau of Plant Industry, Washington, sailed for Europe on April 25 and will spend three months in a study of the progress being made in the investigation of soil bacteriology in Germany, Russia, France and England

DR CHARLES B ROBINSON expects to return to this country about the end of July Dr Robinson has been in the service of the Philippine Bureau of Science for over three years and it is understood has been collecting this spring along the Indo-China coast, a region very little known botanically

ON April 27 Professor R W Wood, of the Johns Hopkins University, began a course of three lectures at the Royal Institution on "The Optical Properties of Metallic Vapors," these being the Tyndall lectures

SIR JOHN MURRAY lectured before the New York Academy of Sciences on April 24, his subject being "The Depths of the Sea" On April 27 he lectured before the Geographical Society of Chicago on "The Ocean" After the lecture the Helen Culver gold medal of the society was conferred upon him

DR JACQUES LOEB, of the Rockefeller Institute for Medical Research, delivered the address at the annual conversational meeting of the Philadelphia Pathological Society, on April 27 His subject was "Fertilizing Effects of the Extracts of Tissues, Blood and Sperm" After the address a reception was given to Dr Loeb at the University Club

PROFESSOR LAFAYETTE B MENDEL, of the Sheffield Scientific School, Yale University, gave two lectures on "Nutrition" at Goucher College, Baltimore, on April 27 and 28

PROFESSOR E L MARK, director of the zoological laboratories of Harvard University, gave an illustrated lecture before the departments of geology and biology of Colgate University on the evening of April 21 His subject was "Some Vestigial Organs in Man"

DR MAXIMILIAN TOCH, head of the firm of Toch Brothers, manufacturers of paints, will give three lectures before the students of the Engineering School of Columbia University, on "Paints, Pigments and Drying Oils" Dr Toch was at one time assistant professor in Columbia

PROFESSOR G W RITCHEY, of the Mount Wilson Solar Observatory, at Pasadena, Cal, gave a public lecture under the auspices of the University of Minnesota Chapter of the Sigma Xi on April 21 on the subject "The Largest Telescope in the World and its use in Photographing the Heavens"

PROFESSOR SVANTE ARRHENIUS, Stockholm, Sweden, will deliver the third Weir Mitchell lecture of the Philadelphia College of Physicians on May 16 The subject will be "The Passage of Microorganisms through Interstellar Space a Theory bearing on the Origin of Life on a Planet"

A LIFE of Mrs Ellen H Richards is to be written with the approval of Professor Richards It is hoped that the story of her life may be of such a character that it will not only interest those who have known Mrs Richards either personally or through her work, but will also serve to extend her influence and to inspire future workers Any material, such as letters, photographs, characteristic sayings and incidents, which will help to show her personality and her interests and activities will be valuable to the editor, Miss Caroline L Hunt, and should be sent to her at 32 Eliot Street, Jamaica Plain, Mass

DR CHARLES STEDMAN BULL, professor of ophthalmology in the medical department of Cornell University, died on April 17, aged sixty-six years

MR T. RUPERT JONES, FRS, formerly professor of geology at Sandhurst, has died at the age of ninety-one years

MAJOR GEORGE LAMB, director of the Pasteur Institute of India and known for his important work on snake venoms, the plague and hydrophobia, died at Edinburgh on April 11, in his forty-second year

PROFESSOR EDUARD ZACHARIAS, director of the Botanical Institute of Hamburg, has died at the age of fifty-nine years

PROFESSOR A HOUZEAU, professor of chemistry in the Rouen Scientific School, has died at the age of eighty-two years

THE eighth annual meeting of the American Society of Tropical Medicine will be held in Tulane University, New Orleans, on May 18 and 19, under the presidency of Dr William S Thayer, of the Johns Hopkins University

WORD has been received from Professor Arthur H Quinn, secretary of the Association of Colleges and Preparatory Schools of the Middle States and Maryland, that the association accepts the invitation of Columbia University to hold the next meeting there The meeting will take place on December 1 and 2, 1911

ON the invitation of the departments of science of Princeton University, the teachers of science in New Jersey schools will hold their annual meeting in Princeton on May 27

IN a letter to Secretary Walcott, of the Smithsonian Institution, dated Bahia Blanca, Argentina, March 17, 1911, Mr Bailey Willis gives the following account of the initiation of the work which he is conducting for the Argentine government

You may care to know what progress we are making in the forty first parallel survey, south latitude We landed in Buenos Aires twenty days ago The topographers have now been at work a week on base line and station signals in northern Patagonia Washburne and Jones, geologists, went out to initiate themselves in the geology of a section that has been studied along the railroad that runs west from this city half way to the Andes Pemberton and I remained in Buenos Aires till yesterday, when we got our outfit aboard the steamer that takes it to Puerto San Antonio in northern Patagonia Now we are off with 120 mules and horses on a 200 mile ride across Pampa and plateau to San Antonio The region is almost waterless south of the Rio Negro We find that there is a basement of gneiss and granite, which comes to the surface here and there There are porous continental sandstones of Tertiary and Cretaceous ages, and also large areas of basalt Their distribution is unknown, but in the course of four or five months we shall know it, and the answer to the water problem will be worked out

IN his recent address at Madison, ex-President Theodore Roosevelt spoke as follows in regard to the University of Wisconsin: "It is not too much to say that the University of Wisconsin occupies a position entirely unique not merely in this country but in the world, as an institution which beyond all others has come the nearest to recognizing the ideals of using the instrumentalities of higher education for rendering the greatest possible service to the country The nation, as a whole, points to this state as the state in which the leading public men are not backed by the ordinary corporations that too many of our public men have been backed by in the past, but by the greatest educational institution in the state, and I have found everywhere on the Pacific slope and in the Rocky Mountains that the ambition of every state was to follow Wisconsin as the wisest and most far seeing progressive state, and to secure the same co-operation in their state between their government and their university in rendering service to the state, which obtains to-day in Wisconsin"

AT a meeting of executive officers of boards of health of New Jersey, held at Newark, N J, on April 17, 1911, a permanent organization to be known as "The Health Officers' Association of New Jersey" was formed A number of the more prominent health officers of the state were present The objects of the organization are, the advancement of knowledge relating to public health and sanitation and the encouragement of social intercourse among health officials The following officers were elected

President—C H Wells, Health Officer, Montclair

Vice president—John O'Brien, Jr, Health Officer, Plainfield

Secretary and Treasurer—J Scott MacNutt, Health Officer, Orange

An executive committee of seven was elected, and the officers, with the advice of this committee, were instructed to draw up a constitution and by-laws for presentation at the next meeting to be held May 17 The membership at present includes as eligible all health officials holding state board of health licenses, and doubtless will be extended to other health

board officials and employees and members of local boards of health Five or six meetings a year will be held for the presentation and discussion of papers Most of the prominent health board officials of the state have expressed themselves as strongly in favor of the association, which promises to grow rapidly in membership and influence

UNIVERSITY AND EDUCATIONAL NEWS

By the will of Ernest V Cowell, the University of California receives a bequest of $750,000 It is for a hospital, a gymnasium and an athletic stadium, each to cost $250,000

The Nebraska legislature has passed a bill, which the governor has signed, appropriating $100 000 with which to begin the development of the campus of the College of Medicine of the university, in Omaha The issue presented in the legislature was whether or not the state was ready to begin the development of a complete medical college plant, and the decision was affirmative, by a narrow margin in the house and by a wide margin in the senate

Dr Elmer Ellsworth Brown, U S Commissioner of Education, has been elected chancellor of New York University

Bruce Payne, Ph D (Columbia, 1905), professor of educational psychology in the University of Virginia, has been appointed president of the George Peabody College for Teachers at Nashville The old Peabody College has been disbanded and President Payne will have a free field in constructing the new one, which is to have new grounds, buildings and faculty, and one million and a half additional endowment

Professor H H Newman, chairman of the school of zoology, University of Texas, has resigned to accept an associate professorship of zoology at the University of Chicago All appointments in zoology at Texas have been made and the details will be made public in a subsequent number of this Journal

Dr Clinton R Stauffer, assistant professor of geology at the School of Mining, Kingston, Canada, has been appointed associate professor of geology in Western Reserve University.

Dr J J Laub, of Heidelberg has been appointed professor of theoretical physics and geophysics in the University of La Plata

DISCUSSION AND CORRESPONDENCE

THE REFORM OF THE CALENDAR

To the Editor of Science A recent letter by Professor Chamberlin in your journal entitled "Reform of the Calendar" has reinterested me in the subject and suggested the publication of another, and, it is hoped, more correct view of the subject A perusal of the article "Calendar" in Encyclopædia Britannica will suggest arguments in its favor, as to recent articles on the subject, time and inclination are lacking for their reading and the risk is run of anticipation on conflict

As the greater part of the eighteen folio pages in the Encyclopædia is under the head "Reformation of the Calendar" or treats of intricate peculiarities calling for reform, the legitimate effect of the article is the conclusion that what is needed and possible is not a reformation, but a

Simplification of the Calendar

Let us then state this as a problem and attempt a solution The Encyclopædia's definition may be condensed to read "A calendar is a method of meting out time into hours, days, etc, for ordinary use" It is therefore a table of measures which establishes certain units of time and defines the relations between them, and this must be so done as to facilitate the transaction of business

A fortunate solution must depend largely on the units employed and Professor Woolhouse gives, as he must, the *solar day* and the *solar year* as two natural and indispensable units, mentioning later the *month* as a natural but not indispensable one Owing to these units being natural, they are incommensurable and simplicity requires the smallest possible number of such units. It would therefore seem advisable to exclude the month from any controlling influence in the calendar.

Let us see how this will look in a more definite and practical form

Suppose that SCIENCE should found the

Calendar Betterment Association

to spread information and enlist interest and influence sufficient to secure the passage of a law something as follows, similar action to be urged in other countries

It is hereby enacted that the *calendar year* 1917 shall end and the *new-calendar year* 1918 shall begin at midnight of the thirtieth day of December, 1917

That a *new calendar* is hereby established requiring

That the years 1918 to 1924, inclusive, shall consist of fifty-two weeks of seven days each, thus giving these years the uniform length of 364 days

That during these seven years the twelve months shall be recognized in their customary order and grouped in the usual four seasons, but with a length of thirty days each for the first two months and thirty-one days for the last month of each quarter Each first month of a quarter will then begin with Monday, the second with Wednesday and the last with Friday, and all thirty first days will fall on Sunday

That the dates in existing legal papers, or future ones which may mention months, shall apply to the months of the new calendar, in which the first days of January, February, June, August, September and November will take the place of the suppressed thirty-first days of the preceding months

That the dates in all legal papers made under this new calendar shall be expressed by stating the day of the week, the number of the week and the year, the weeks being numbered in succession from the beginning thereof and the days of the week from one to seven, or named as usual, from Monday, the first day, to Sunday, the last. When the date is expressed in fractional form the numerator shall be the number, or name, of the day and the denominator that of the week, thus the first Tuesday in 1918 will be 2/1 1918 or Tu/1 1918, and the last Saturday 6/52 1918 or Sa/52 1918, and the date may be underscored when confusion might occur with an old calendar date For relatively unimportant purposes these dates may be written thus 20118 and 65218

That during the *common years* previous to 1925 the necessary adaptations of business procedure to the occurrence of *long years* of 53 weeks each shall be made

That as the year 1924 will end about the shortest day, and as certain of the calendar years must be lengthened to make their average the natural length, the year 1925, and every fifth year thereafter, shall be a *long year* of 53 weeks, with the exception of the year 1950 and subsequent years divisible by 50, which shall be common years

That for a still closer adjustment the years 1995, 2395, etc, at intervals of four hundred years shall be changed back to common years of 52 weeks each

That no further adjustment is to be anticipated for 25,000 years

That after 1/1 1925 all legal and business documents shall be dated by the day, week and year, and periods of time shall be stated in days, weeks and years, and that so stated a year shall be held to mean 52 weeks, and that when a year of 53 weeks is intended it must so be stated or the term "*long year*" used

It was my first intention to write a criticism of the calendar proposed in the letter referred to, but on a visit to an old friend shortly after its publication we discussed it and also my system, which he urged me to put in print. From the point of view of the writer of the letter, which my friend somewhat favored, the calendar he proposes has much to recommend it It is certainly picturesque, too much so for business purposes, but not enough for ecclesiastical If the definition of a calendar could be changed to make it a piece of tapestry to decorate the seasons, it might be acceptable in America with publishers of calendars and others on the ground that people here are too practical and lack in artistic feeling, and need something of the kind to educate them to appreciate the beauties of the church calendars, but business people want a plain calendar

After writing the above an accidental opening of your issue of December 23 shows me a similar proposition for correction by weeks from the University of Illinois, where for some years astronomy was in my charge, but the arrangements proposed bring to mind a passage in the Encyclopædia which says "The difficulties that arose in attempting to" adjust differences "induced some nations to abandon the moon altogether" Wise nations! To the escaping Hebrews the moonlight was all-important, but if we were to run away we should most likely depend on artificial light and may safely abandon the moon

A discussion in detail of the feasibility of the correction by weeks would be too long for a single letter My hope is that it may be exhaustively criticized and prove to be the easiest way One five-yearly correction large enough to be intelligently provided for ought to be better than numerous small and confusing irregularities

Comparatively such a correction is not large For the sake of uniformity we now have "standard time" varying as much as two per cent from local time, local noon varying as much as one per cent from astronomical, and we have months differing in length by ten per cent, with similarly large differences between the calendars of different nations The proposed correction is less than two per cent

Some of the details have been worked out in tabular form to the year 2006 and further, but this letter is long enough without the insertion of tables The general effect of the proposed calendar on New Year's Day is to shift it towards the shortest day of the year, but by 1946 and 1991 it has returned to its present place, after 1991, however, it creeps back more permanently so as to remain among the shortest days of the year

J Burkitt Webb

To the Editor of Science If calendar reform is going to be a subject of discussion in scientific circles, international conferences, etc, it would be well to bear in mind that any radical change will be a great inconvenience to the business world I agree with Professor Barton[1] that the disadvantages of Professor Chamberlin's scheme outweigh its advantages

We can not have an ideal calendar for the reason that 365 is not exactly divisible by 12, 10 or 8 The year has been divided into twelve months for thousands of years, and it is as satisfactory a division as can be made, especially since the twelve months are divisible into four quarters The chief objection to the present calendar is that February has only 28 days This can easily be changed by giving it 30, and taking the two days from some of the months that now have 31 I suggest the following

Five months of 31 days December, January, June, July, August—155 days

Seven months of 30 days February, March, April, May, September, October, November—210 days

February may be given 31 days in leap year

December, January and July each have now a national or general holiday We can shift Memorial Day to June and Labor Day to the last working day in August, so that each month of 31 days would have a holiday in it

Wm Kent

The movement for the reform of the calendar has just made new progress We learn from M Grosclaude, inventor of the chief project, and also by official confirmation through the newspapers, that the Swiss Federal Council has decided to initiate the calling of an international conference, whose purpose will be the reform of the Gregorian calendar, in order to obviate the inconvenience caused by the changing of the weeks in the year, which brings the school holidays at different times each year

The Vatican has been consulted and would be in favor of the reform, which would remove the necessity for changing the date of Easter every year

The reform to be discussed will be based on the project of Grosclaude, which has already been explained in these columns, and which was recommended by the first congress of the Universal Esperanto Association last August

It is therefore to be hoped that soon this important reform will be on the way to realization

[1] Science, January 13

If the Swiss government had not taken the initiative in the matter, the government of the Netherlands was and is yet willing to call a conference for the same purpose

During the past few months SCIENCE has devoted a great deal of space to the above subject, and several well-developed schemes for improving the calendar have been advanced However, none of these schemes has been complete, and none of the authors of them has presented with his scheme a plan by which it could be introduced

The above quotation is a translation from Esperanto of a news item which appeared in the issue for December 5, 1910, of the official organ of the Universal Esperanto Association, published at Geneva, Switzerland It speaks of a scheme for improvement of the calendar that has been under discussion in Europe for more than twenty-five years, but which, strange to say, has never been published in this country This plan was originally published anonymously by Camille Flammarian in 1884 and afterwards by M Armelin, of Paris, in 1887 In 1900 it was revived by L A Grosclaude, of Geneva, and it is known as Grosclaude's project It has been developed to its present stage by scientists of various nations in the *Internacia Scienca Revuo*, published in Dresden, by means of the language Esperanto In the recent discussion the original plan has been slightly modified in accordance with ideas advanced by Professor Dr W Koppen, of Hamburg, and the scheme as here presented is now advocated and supported by Dr Rene de Saussure, a well-known scientist of Geneva

As will be seen from the following explanation and the accompanying table, the compilers of this scheme have achieved a wonderful simplification of the Gregorian calendar, which can be introduced with absolutely no break in present dates and no interruption of present customs

There are just three great evils in the present calendar, and these are (1) The constant changing of the position of the weeks in the year, (2) the great irregularity and inequality of the lengths of the months, (3) the necessity for movable holidays on account of the changing of the weeks each year

As the third evil is caused by the first, there are really only two points which need to be changed in the present calendar These are (1) To fix the weeks in the year, and (2) to even up the lengths of the months

As there is just one day more than fifty-two full weeks in an ordinary calendar year, the obvious solution of the problem of the changing weeks is to make this day a non-week-day Having done this, the fifty-two weeks may be divided into four quarters of thirteen weeks each As each quarter has ninety-one days, it may be divided into three months—one of thirty-one days, and two of thirty days A little calculation demonstrates that the logical place for the thirty-one day month is at the beginning of the quarter, as this arrangement makes it unnecessary to change the length of more than five of the months, the other seven months remaining exactly as at present

By placing the non-week day at the end of the year, it may be made the thirty-first of December, thus remaining a part of the month and of the year, although not a part of any week

As the thirty-first of December is St Silvester's Day, and is celebrated quite extensively in some sections in Europe, it is proposed to call the non-week day *Silvester* and to make it the holiday, instead of January first as at present

As the first day of the week is Sunday, each quarter must begin on Sunday in order to have thirteen complete weeks in each quarter January first would therefore fall on Sunday, and "Silvester" would come between Saturday and Sunday

In leap years, the leap-year day would also be made a non-week day and would be placed at the end of the first half-year, thus becoming the thirty-first of June, and giving the first half year the same number of days as the second half It is proposed to call it *Leap-year Day*

This plan makes a peculiarly happy disposition of the holidays, movable, as well as fixed, as may be seen by the accompanying

table of fixed dates It combines all the best points of the proposals that have been published in these columns, and avoids their bad points

The plan for its adoption has all the simplicity that usually accompanies really good things and is as follows

In the year 1911, the days of the week in the months of September, October, November and December coincide with the arrangement in the proposed calendar If, any time during the year 1911, the governments of the various nations will decide to declare the thirty-first of December of that year, and of all future years, a non-week-day, one half of the problem will have been solved If they will then declare that during the year 1912, and all future years, the number of days in the five months February, March, April, May and August shall be changed in accordance with the accompanying table, the entire problem will have been solved

As this is a perfectly simple, practical and conservative plan for overcoming difficulties that every one is obliged to contend with every day of his life, steps should be taken by those in a position to do so, to have the president authorized to appoint a commission to investigate the matter thoroughly, with authority to confer with the similar commissions to be appointed by other governments and by the Vatican, to the end that some such scheme shall be adopted

The conditions necessary for the adoption of this scheme as outlined above will recur in 1917, and as it is hardly likely that any scheme can be agreed upon by December, 1911, we may look to that year to free us from the inconveniences under which we have suffered so long

QUOTATIONS

THE GOVERNMENT OF UNIVERSITIES

AMERICANS interested in the questions of university government will find much that is interesting and pertinent to our own situation in the admirable article on "Modern Universities and their Government" which is the leading feature of the London *Times's* educational supplement for April 4 We are very much in the habit of thinking of our universities, with ultimate power over the institution resting in the lay boards of trustees, as being in this respect quite unlike any other educational institutions of similar importance, and this is natural enough, since the half-dozen new universities that have been established in the chief provincial cities of England, and which are probably their only important analogues, are of such recent origin as to be seldom prominently in our thoughts in this connection It is the government of these new universities, and especially the methods and the spirit of their procedure in the appointment of professors, that constitute the subject of the *Times* article, a subject justifying the extreme seriousness with which it is discussed because the universities in question are expanding with such rapidity that they "have to a large extent the future of English learning in their hands"

Both the resemblances and the differences that suggest themselves, as between the American and the English experience, are of decided interest Into the details of the English organization we shall not attempt to enter, suffice it to say that the active governing authority of the university, corresponding to our board of trustees, is what is known as the council, and while this council is not nominally self-electing or self-renewing, in practise it is so Perhaps the most interesting state-

ment made about the councils is that which refers to the personal attitude of the members who constituted those bodies in the first place, and to the signs of a change which seems to be more or less in danger of showing itself as matters settle down to a more mechanical routine. The large prospect of creative utility which the foundation of the provincial universities opened up attracted the services in their councils of some of the ablest business men in England, who felt that they were privileged to take part in the building of great institutions of national importance. "And, being large-minded men," says the *Times* writer, "they have usually recognized the limits of their own competence, and know what matters to leave in the hands of the experts. They have respected and trusted the scholars by whose presence their cities were enriched." In some of the successors of these large-minded men, a tendency has been observed to depart from this fine attitude. "The smaller man is apt to have less respect for and less trust in the scholar than the bigger man, and a more serene confidence in his own capacity as a 'business man' to deal wisely with any and every question that may come before him."

Speaking broadly, it is safe to say that while our boards of trustees have furnished illustrations of both of these types of attitude and conduct, neither their merits nor their defects have been so pronounced as the *Times* article represents to be the case in England. Many trustees of American universities, however, have done a great amount of important and unselfish service, animated by that same feeling of the honor and the usefulness of their posts as obtained with the able men who helped to build up the new English universities, while, on the other hand, the instances of pretentious or ignorant meddling by trustees have been very rare in this country, in the case of universities of high standing and importance. But this abstention from harmful interference on their part has been accompanied, in most cases, by that abnormal concentration of power in the hands of the university president which has formed so prominent a subject of recent academic controversy.

It is a notable circumstance that, varied as are the methods of selection discussed in the *Times* article, there is not a word of discussion as to the tenure of the professor after appointment. That a professorship should be a life position it does not seem to occur to any one to question. The defects that exist in regard to the matter relate entirely to the way in which the selection is made. In this respect great differences exist, some of the university councils proceeding upon exceedingly crude "business" notions of the way in which the best man is to be found, while others have established methods that are, in the opinion of the *Times* writer, the best that could possibly be devised. In these cases, the most careful inquiry is instituted, in the first instance, by a committee of the particular faculty concerned, an inquiry which results in the adoption of different methods—including, when necessary, that of advertisement—according to circumstances, the senate considers the result of this inquiry, and then makes its recommendation of a particular person to the council, giving "a full and reasoned statement" of the grounds for its choice. Of course, this recommendation is usually adopted without question, but the process, with a council of the right sort, is evidently a wholesome one. It is not altogether different from that obtaining in some of our own universities, but what strikes one in reading of it is the profound realization of the importance of making the best possible choice. This, as well as the permanency of tenure, is sure to have a powerful influence in the preservation of the ideas of dignity and importance which ought to attach to the post of a university professor, and it is evident that in England as well as with us much will depend on the vigor with which, now and in the near future, those ideas are insisted on by the public opinion in the educational world. "Lay hands suddenly on no man," but, having chosen him, let him feel that his position is assured—this is the rule that must guide in professorial appointments if we are to get the maximum of that real

university efficiency which can not be measured by any mechanical tests, but which has its root in the personality of the professors —*The New York Evening Post*

SCIENTIFIC BOOKS

A Directory of American Museums Compiled by PAUL MARSHALL REA Being No 1, Volume X, Bulletin of the Buffalo Society of Natural Sciences 8vo, pp 360 Buffalo, N Y 1910

The object of this directory is to give, as far as possible, a complete list of the museums of America, using the word in its broad sense, with information as to their purposes, character and extent of their collections, mode of support, manner of administration, staff and publications, with a brief sketch of the history of each institution It is arranged alphabetically by states and cities, and, with the index, comprises 360 pages, 313 being devoted to the museums of the United States The collections are listed mainly under certain specified headings, anthropology, art, botany, geology, paleontology, zoology, and the approximate number of specimens on exhibition and in the study series is stated Great pains have been taken to have this information as exact as possible, and it will be found that in many cases there is a very considerable reduction in the size of collections from that noted in the list prepared by F J H Merrill and that in a few instances there is stated to be "no museum," where one was said to exist in 1903

The data given, checked by the character of the financial support, and a knowledge of the staff, will furnish a pretty good idea of the size and importance of the institutions noted

The preparation of the work was authorized in 1908 at the second meeting of the Association of American Museums and the arduous duty of gathering the information and making it ready for publication was performed by Paul M Rea, secretary of the association The cost of issuing the work, which has been considerable, was generously borne by the Buffalo Society of Natural Sciences It was hoped to have had the directory issued as a memorial of the Buffalo meeting of the association, but owing to inevitable delays in securing needed information it did not appear until late in 1910

As the only directory of American museums previously issued is that prepared by F J H Merrill and published in 1903, by the education department, state of New York, this volume is very welcome We should have been glad of a brief summary, giving the number of museums in the United States, their total annual expenditure and the number of their staff, but this may well be left for some one interested in the study of statistics

In conclusion it may be said that if, as Dr Goode considered, the museum is the most advanced of institutions for the education of the public the United States stands well to the fore F A LUCAS

Studies on the Structure and Affinities of Cretaceous Plants By MARIE C STOPES and K FUJII Phil Trans Roy Soc, London, Series B, Vol 201, 1910, pp 1–90, pls 1–9

A glance at the above somewhat impressive title might lead one to presume that we have to do with a paper of broad, possibly worldwide, scope, and it is not until we reach page 4 that we learn incidentally that it deals exclusively with material from Hokkaido, northern Japan Here the authors have been exceedingly fortunate in securing nodules—presumably silicified—in which are preserved fragments of vegetation which indicate the presence of a varied and interesting flora, and suggest, in the manner of occurrence, the English Carboniferous nodules which have yielded such splendid results to Williamson, Scott and others It is much to be regretted, however, that the present paper does not give more explicit information regarding the geological position of the material, the only data on this point consisting of the following statement "In nearly every case there are parts of shells of Ammonites in the nodules These have been described by Yabe, and there is no doubt, as a consequence, that the plants are of Cretaceous age" That the description of the

Ammonites by Yabe necessarily proves the Cretaceous age of the plants may, or may not, be true, but it can hardly be accepted as very definite information in itself, since Ammonites had their origin in the Triassic. Even if they are located in the Cretaceous or "Upper Cretaceous" it is not sufficiently close to permit of comparison with horizons of definite stratigraphic positions in the Cretaceous of other parts of the world. But this study avowedly was made, not from the standpoint of geological paleobotany, but from the professedly higher plane of histology, and as such it must be judged.

Those paleobotanists who, although perhaps not entirely without knowledge or appreciation of the value of structure, have made widest use of the impressions of plants, have had held before them the dictum that structure is the only road that leads to permanent accomplishment—a sort of Nirvana, as it were, which few could hope to attain. It was therefore with particular pleasure that we turned to the present paper in the hope that we should find an exposition of paleobotany founded on the solid basis of internal structure. The reviewer confesses to a feeling of disappointment.

Of the eighteen new genera and species, which range from fungi to angiosperms, it appears that hardly any is of absolutely definite position and affinity. Thus, of the fungus (*Pterosphæria*) our authors say, "the lack of characteristic spore-bearing fructifications makes its exact location impossible." Of the two forms described as ferns, the first (*Schizæopteris*) is thought to belong to the Schizæaceæ, but its affinity is uncertain, while the other (*Fasciostelopteris*) is balanced between the Cyatheaceæ, Marattiaceæ and Dicksoniaceæ, and the conclusion is reached it "may therefore for the present be provisionally included in the Dicksoniaceæ." *Nipponophyllum cordaitiforme* is a leaf, and here now is the opportunity to see what can be done with internal structure as compared with an impression. After meandering through the better part of five quarto pages in seeking affinities balanced between Araucarineæ, Podocarpineæ, various genera of cycads, as well as *Cordaites*, we have the following: "Was the plant to which our leaf belonged a primitive type of cycad, or perchance a belated, small-leaved *Cordaites* surviving in this island of the orient, just as the truly archaic *Ginkgo* survived to the present geological epoch?" Since *Cordaites* had its maximum development in the Carboniferous and did not, so far as we definitely know, survive beyond the close of the Paleozoic, this discovery is of interest—if true! Their new species of *Cedroxylon* might belong, they state, either to this genus or to *Cupressinoxylon*, while the "new" coniferous genera *Yezonia* and *Cryptomeriopsis* have recently been reviewed at length by Professor Jeffrey.[1] The Anglo-Japanese authors state of their *Yezonia*: "It is impossible to find any family among gymnosperms with which we can satisfactorily include this plant," but Jeffrey shows conclusively that it is the same as *Brachyphyllum* from the Cretaceous of Staten Island, adding "if all the points of agreement between the description of the supposed new genus *Yezonia* ... and the account of the anatomy and habit of *Brachyphyllum*, given in the present article and in the large memoir of Dr. Hollick and the present author were italicized, it would be necessary to italicize the whole description"! Their *Cryptomeriopsis* is shown by Jeffrey to be merely the old *Geinitzia* (*Sequoia*) *Reichenbachi*, that has been known from impressions since 1842.

The several angiosperms described are, if possible, in an even more unsatisfactory state as regards definiteness, and the authors acknowledge that "from the anatomy of stem and rootlets alone it is a matter of extreme difficulty and some uncertainty to determine the affinity of an angiosperm." Thus of their *Jugloxylon* they "lay no particular stress on the systematic position that the name suggests." *Populocaulis* agrees with *Populus* "more closely than with any other," while *Fagoxylon* has "general affinities with the whole Cupuliferæ," which is certainly sufficient leeway. The only angiospermic fructifi-

[1] *Annals of Botany*, Vol. 24, 1910, p. 767.

cation that came to light our authors had some difficulty in placing, finding it hard to decide whether it belonged to the dicotyledons or monocotyledons, but as a final conclusion they say "On the whole, judging from its detailed structure and general appearance, we incline to place the flower in the Liliaceæ" Is it to be presumed that such adumbrations as the above add much to the evolutionary history of the Liliaceæ, or of the monocotyledons in general?

It is not necessary to further mention the technical portion of the paper, and it only remains to call attention to some of the nomenclatorial anomalies All the genera and species published as new to science in the present paper were printed a year earlier in the *Geological Magazine*, London, N S, Vol 6, 1909, pp 557–559, but without characterization They are all again listed on page 1 of the paper under review, some of them incidentally mentioned at various places in the introduction, each again appearing at the head of the section of the text in which it is described, while at the end of the description there is a formal generic and specific characterization where each is called "gen nov," or "sp nov" The question arises as to how these shall be cited To give *Cryptomeriopsis* as a concrete example Shall we quote page 1 of this paper, where it is first printed; page 3, where it is mentioned and partially described, page 52, where it stands at the head of the description, or page 57, where the genus and species are formally dedicated?

The reviewer does not wish to be understood as in any way underestimating the value of histology in establishing a firm basis on which to work out the developmental history of plants, but if the study of the internal structure of fossil plants, as contrasted with the study of plant impressions, is to be given proper weight it must be subject to the same scrutiny If the study of the intimate anatomy of fossil plants leads only to indefiniteness and inconclusion, it is not entitled to greater weight than attaches to the study of the impressions of plants

F H. Knowlton

SOME RECENT ADVANCES IN FLUORESCENCE AND PHOSPHORESCENCE[1]

After an opening period of great activity, which began with Becquerel, Herschel and Stokes and included the important work of Lommel, Wiedemann and Schmidt and of numerous other physicists, there was a long time of comparative quiescence during which *luminescence,* to use the word proposed by E Wiedemann, was a neglected branch of optics Quite recently there has been renewed activity in this field and it is of some aspects of this newer work that I shall try to give a brief account No approach to a complete summary can be made in a single paper and I shall deal chiefly with certain investigations which are particularly suggestive of the beginnings of correlation in this involved and obscure portion of the science of radiation

The Relations of Phosphorescence to Fluorescence —The common view that phosphorescence is simply what remains of fluorescence after the cessation of excitation would seem to need essential modification according to the latest paper of Lenard,[2] who, after extending his observations to some fifty phosphorescent compounds, made by the addition of a trace of some metallic salt to a sulphide of strontium, barium or calcium and certain heat treatment with a flux, considers that it is necessary to distinguish two phenomena, the one temporary, which ceases almost instantly after the end of excitation (*Momentan-process*), and the phenomenon of long-time phosphorescence (*Dauer-process*) The distinction is three fold · The momentary process may be produced independently of the other (1) by very brief excitation, (2) it may be excited by the use of portions of the ultra-violet spectrum which are incapable of producing long time phosphorescence or (3) at temperatures above or below the range within which long-time phospho-

[2] Lenard, *Annalen der Physik* (4), Vol XXXI., p 641, 1910

rescence can be excited Lenard regards the phosphorescence spectrum as consisting of one or more well-separated, broad and continuous bands usually lying within the visible spectrum Detailed study of these bands with the spectrophotometer,[3] however, shows that they are really of a very complex structure and consist of overlapping components which can not be separated altogether for any given temperature or mode of excitation, but which are so differently affected when the wave-length of the exciting light is varied or when excitation occurs at different temperatures, as to indicate that they are not due to the luminescence of one and the same molecule or aggregate It is probably on account of this complexity of the phenomena that Lenard has reached his view of the case Certainly the evidence of recent work by Pierce,[4] Waggoner[5] and Zeller[6] goes to show that whatever may be true of phosphorescent sulphides prepared by the method of Lenard and Klatt, the relation between phosphorescence and fluorescence is in many other instances the intimate one that has usually been assumed to exist

Fluorescence in the Ultra-Violet and the Infra-Red—Stark and Meyer[7] have in a recent paper shown the existence of numerous fluorescence bands lying in the ultra-violet spectrum In the case of the benzol derivatives with which their measurements have to do fluorescence depends for its position upon the complexity of the molecule and it is found that, as a rule, the heavier aggregations have bands in the longer wave-lengths

Steubing[8] finds spectrum lying at still shorter wave-lengths (.1884μ) which he ascribes to the fluorescence of oxygen This spectrum, like the corresponding spectra for vapors of gases having fluorescence in the visible spectrum, as described by Wood,[9] consists of a group of bands regularly but not uni-

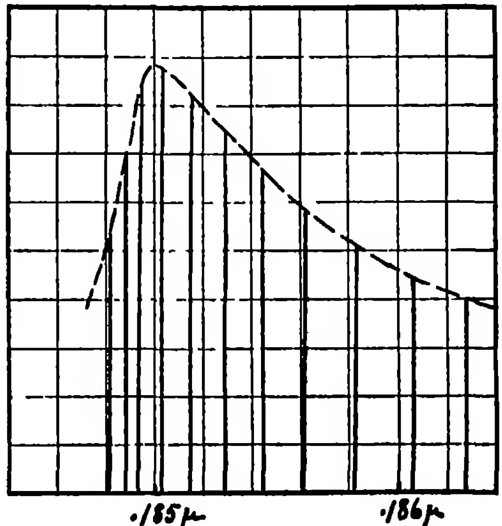

FIG 1 Diagram showing the distribution and relative intensity of bands in the fluorescence spectrum of oxygen (Steubing)

formly spaced As may be seen in Fig 1 the distance between the bands increases gradually with increasing wave-length Beginning at that end of the group which lies furthest in the ultra-violet, the intensity of the individual bands rises very rapidly to a well-marked maximum and falls off more slowly as the wave-length increases An inspection of the remarkable photographs made by Wood of the fluorescence of sodium and other vapors leads one to believe that were measurements made of those spectra a similar distribution of intensities would be found to exist.

Pauli[10] has recently subjected the preparations of Lenard and Klatt to systematic study, particularly with the view of corroborating Lenard's hypothesis that the active metallic atom embedded in the sulphide is to be re-

garded as an electric oscillator, the period of vibration of which depends upon inductance and capacity. By modifying the dielectric constant of the solvent it was found that the position of the fluorescence band could be altered at will and Pauli succeeded in producing preparations having bands in the ultra-violet only and in other cases only in the infra-red.

The Complexity of the Fluorescence Spectra of Solids.—The complexity of fluorescence spectra which was first so strikingly exhibited in Wood's studies of sodium vapor is by no means confined to gases. Not only do we have solids whose spectra are made up of overlapping bands due to the presence of several fluorescing constituents, as in the case of the sulphides of Lenard and Klatt, but there are also substances of definite chemical composition, notably the uranyl salts, the fluorescence spectra of which consist of a group of several bands arranged in a manner which suggests the banded spectra of gases. E. Becquerel[11] in 1872 studied these fluorescence bands and discussed their relations to the corresponding absorption spectra. The subject has since received the attention of numerous investigators, the most recent contribution being that of Jones and Strong.[12] Henri and Jean Becquerel,[13] working at Leiden with Kamerlingh Onnes, have studied the fluorescence spectra of uranyl salts, photographing the same at 288° of the absolute scale, 80° (liquid air), 20° (liquid hydrogen) and 14° (solid hydrogen). Under these conditions the already unusually narrow bands are reduced to mere lines in the spectrum and each band is found to consist of a group of such lines.

The relation of the narrow fluorescence bands of the uranyl salts to the broad bands in the fluorescence spectra of other solids and liquids is not at first sight obvious. They appear to be intermediate between the broad bands usual to solids, of which sometimes only one exists, and the complicated groups of lines observed in the case of vapors. Some recent studies of the uranyl bands appear, however, to throw some light on this relationship.[14] Hitherto attention has chiefly been directed to the location of the bands in the spectrum. When, however, we measure the relative intensities of such a group of bands we find them to be related in a very interesting manner. The curve showing the relation between wave-length and intensity of the seven strongest bands in the fluorescence spectrum of such a salt has a form which is essentially identical with that of the typical curve for the distribution of energy in the broad single bands of ordinary fluorescence spectra. The shape is the same for the various uranyl salts, being shifted slightly in wave-length with the chemical composition or with the presence or absence of water of crystallization.

Fig. 2 will serve to indicate the characteristic form of these curves and the shift

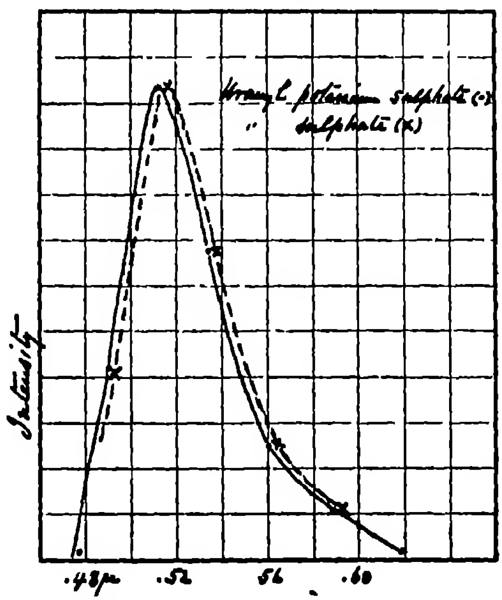

FIG. 2. Relative intensities of the seven principal bands in the spectra of two uranyl salts.

due to change in chemical composition The examples selected are uranyl sulphate ($UO_2SO_4\ 3H_2O$) and uranyl potassium sulphate ($UO_2SO_4\ K_2SO_4\ 2H_2O$)

That this relation is not an accidental one, but that these various bands are probably due to the oscillations of one and the same complex mechanism may be almost conclusively established by observing the spectrum under various conditions of excitation and of temperature When we subject accidental combinations due to different substances in a fluorescing mixture to such changes the independence of the various components is readily shown, but in the case of the uranyl bands when excited by the monochromatic light of various lines of the mercury arc from 4538μ to 2536μ it is found that the relation between the intensities of individual bands remains very nearly the same When the substance is gradually cooled to the temperature of liquid air and observations are made at intermediate temperatures, it is found that all of the bands shift towards the violet and that their gradual movement as the temperature changes is of the same character for all The relation of intensities in this case does not remain the same, but it is significant that the changes are such as to produce a modification in the curve of relative intensities precisely similar to that which is known to occur in the case of the ordinary broad continuous fluorescence bands when the excited substance is cooled It would therefore appear that we have in the case of the fluorescence of the uranyl compounds a single fluorescence band of the usual type but broken up into several easily separable components It is easy to imagine that a continuance of the change which occurs in the fluorescence of these substances as the temperature rises from that of liquid air to $+20°$ C would result in the merging of these components into a continuous band in which they could no longer be distinguished from one another

In the case of some of the uranyl salts, indeed, the overlapping of the bands is considerable under ordinary conditions, as may be seen in Fig. 3, which is from measurements of the three strongest bands of uranyl nitrate at 20° C

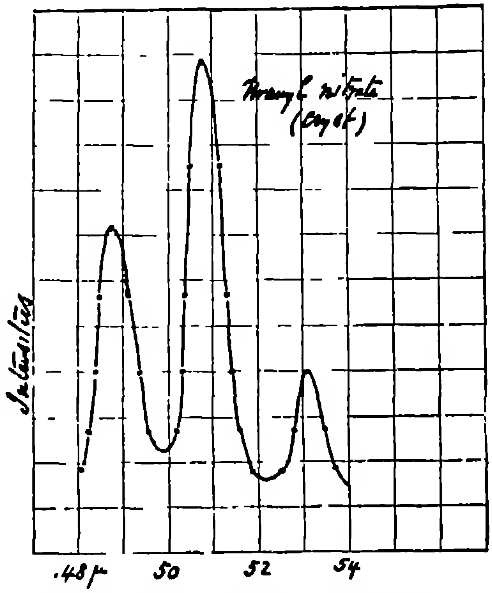

FIG 3 Diagram showing the overlapping of the three principal bands in the fluorescence spectrum of uranyl sulphate

The relation may be carried still further when we consider that the broad continuous bands of fluorescent substances are always associated with a broad absorption band usually overlapping the fluorescence band on the side toward the violet and that the absorption spectrum of the uranyl salts consists of a series of bands precisely similar as regards their arrangement and number to the bands of the fluorescence spectrum This group of bands according to E Becquerel is to be regarded as a continuation of the series of fluorescence bands It has been shown by H. and J Becquerel and Onnes[18] to overlap the group of fluorescence bands According to their photographs the bands nearest the red in the absorption group when observed at the temperature of liquid air are nearly if not quite coincident with the last ones of the fluorescence group towards the violet

As in the case of the fluorescence bands of the uranyl salts, the absorption bands increase

[18] Becquerel and Onnes, *l c*

in intensity as we pass from either end towards the middle of the group, and we may depict the relation of the two groups by drawing the enveloping curve for the region of absorption and for that of fluorescence and showing the extent to which they overlap, as in Fig. 4. While detailed quantitative studies of the absorption bands have not yet been made, the preliminary observations indicate that the enveloping curve is an "image" of that of the group of fluorescence bands, just as the broad absorption band of resorufin and other fluorescent substances has already been shown[18] to be the overlapping image of the corresponding fluorescence band.

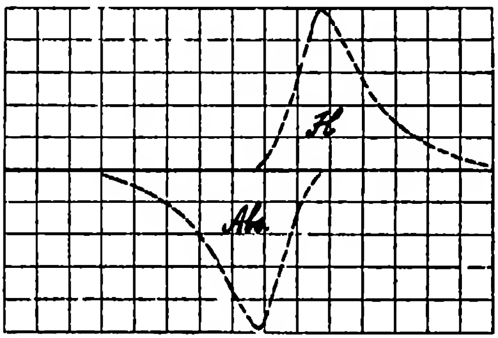

FIG. 4. Diagram showing the overlapping of fluorescence and absorption in the case of a uranyl salt.

Not only is the envelope of the fluorescence group of the same type as the curve of distribution of energy in ordinary fluorescence bands, but each component, as has been shown by spectrophotometric measurements, has a similar distribution of energy. Moreover, both curves have the same characteristics, although with very different scales of wave-length, as the energy curve of the temperature radiation of a black body. That the relation between the luminescence of solids and liquids and that of vapors is an intimate one is strongly suggested by the comparison of the diagram from Steubing's measurements of the fluorescence of oxygen (Fig. 1) with the curves for the uranyl salts just described, and this suggestion is strengthened by the inspection of Wood's curves for the fluorescence of sodium vapor. Moreover, the family resemblance of all these related cases of banded fluorescence spectra to the banded spectra of gases as we find them described in the papers of Deslandres and of Kayser and Runge is unmistakable. In view of these numerous indications of a common property may we not anticipate the attainment of some broader generalization concerning the various types of radiation than has hitherto been made?

NOTES ON THE PRELIMINARY REPORT OF THE COMMITTEE ON THE TEACHING OF MATHEMATICS TO STUDENTS OF ENGINEERING

AT the meeting of the Society for the Promotion of Engineering Education held at Madison, Wis., in June, 1910, the members present were handed sets of galley proofs of the Preliminary Report of the Committee on the Teaching of Mathematics to Students of Engineering, which committee was appointed at a joint meeting of the American Mathematical Society and Sections A and D of the American Association for the Advancement of Science in December, 1907. The committee consists of twenty members, ten of them being professors of mathematics, three presidents of technical institutions and seven professors of engineering and consulting engineers.

The report being only a preliminary one, it is subject to amendment before being presented as a final report, and no doubt the members of the committee will be glad to receive any suggestions which will tend to make the report more useful and more acceptable to engineering teachers. The writer acknowledges the great value of the report as a whole, but he has some criticisms to offer on one portion of it, viz., elementary dynamics, which he hopes will be carefully considered by the members of the committee and by others interested, who may be led by it to offer the committee additional suggestions.

In the preface to the report it is said:

The defects in the mathematical training of the student of engineering appear to be largely in knowledge and grasp of fundamental principles,

and the constant effort of the teacher should be to ground the student thoroughly in these fundamentals, which are too often lost sight of in a mass of details

The defects mentioned are universally admitted and complained of, and they are perhaps more apparent in the subject of elementary dynamics than in any branch of pure mathematics, but the writer is of the opinion that they are due rather to the text-books than to the teachers As the committee says "What is most needed at the present time is a series of synoptical text-books which shall present in compact form (1) the fundamental principles of the science, and (2) a classified and graded collection of problems"

The writer heartily commends the two following sentences in the report

> The poundal is never used in practise, and no instruments are on the market which give readings in poundals, it should be dropped from the text books The so called "engineers' units of mass," namely, the G kilogram, or "metric slugg," and the g pound, or "slugg," are never used in practise, and no set of weights is on the market giving readings in terms of these units, they should be dropped from the text books

The chief trouble with the text-books is due to the fact that some early writer, in his attempt to overcome what he conceived to be a difficulty in teaching the subjects of weight and mass, invented the "poundal," and others invented the "engineers' unit of mass," "gee-pound" or "slugg" (32 2 pounds of matter), to overcome the imaginary difficulty, and other text-book writers blindly followed them These devices did not overcome the difficulty, but on the contrary only created confusion, and students had to spend weary hours on these worse than useless units, which afterwards, when they became engineers, they had to unlearn.

The idea of the "poundal" is probably a development of the "C G S" system, in which 1 dyne (force) acting on 1 gram (matter) free to move, for 1 second, gives it a velocity of 1 centimeter per second. In English units, if 1 pound force acts for one second on 1 pound of matter, the velocity at the end of the time is 32 2 feet per second If the English system only had either a unit of force = 1/32 2 pound, or a unit of quantity of matter = 32 2 pounds, then the figure 32 2 in the equation of the relation of force to acquired velocity would disappear, and the equation would look simpler, so the two new units, poundal and gee-pound, were invented, to the confusion of the subject, and they now have to be expunged from the language

Merely getting rid of the poundal and the gee-pound, however, does not get rid of the whole trouble arising from the use of the same unit, pound, to express both a force and a quantity of matter The committee (or perhaps only one or two members of it, to whom were assigned the subject of dynamics) have wrestled with the problem, but in the writer's opinion they have failed to find the best solution of it

In order to make this criticism as clear as possible, the following extracts are first made from the committee's report, and comments on the several paragraphs follow

Extracts from the Report

(*a*) The most important mechanical quantities for engineering purposes are length, time, angle and force Derived from these are area, volume, pressure, linear velocity, etc

(*b*) Less important for the engineer, but of great importance in general scientific work, is the quantity called "mass" (galley 39)

(*c*) The units of mass are of little importance to the engineer, since the quantity that enters into the equations of engineering is not the mass of the body, in units of mass, but its normal weight, in units of force

(*d*) The mass of a body may be thought of, roughly, as the amount of matter in a body (galley 40)

(*e*) The ratio W/g for a given body is constant in all localities This quantity, or a quantity proportional to this ratio, is called the *mass*, m, of the body (galley 35).

(*f*) The weight, W, of a body, at a given place, is the force that causes it to fall when unsupported (galley 34).

(*g*) If the mass of a body is one pound

(mass) then its normal weight is one pound (force) (galley 35)

(*h*) The normal weight, W_o, of a body is its weight in vacuo, at sea level in latitude 45°.

(*i*) A "set of standard weights" is a set of metal pieces each of which is marked with its normal weight

(*j*) The process of weighing a body on an equal arm balance, against a set of standard weights, gives the normal weight of the body

(*k*) The process of weighing a body on a *spring balance*, on the other hand, gives the *local weight* of the body

(*l*) To graduate the scale of a spring balance find the local weight of a set of standard weights as just explained (by computation from the value of g at the locality in question) and then suspend the pieces successively on the spring, and mark on the scale the deflection caused by the local weight of each piece (galley 34)

(*m*) Force may be thought of, roughly, as a push or a pull

(*n*) $F/W = A/g$ is taken as the fundamental equation

(*o*) If in the fundamental equation $F/W = A/g$ we substitute the equation for mass, $m = c(W/g)$, where c is the numerical factor depending on the choice of units, we have $cF = mA$ Any system of units which makes $c = 1$ in this equation is called an absolute system of units

(*p*) The equation $F = mA$ will give incorrect results if the forces and masses are given in any but absolute units In particular it should never be used in the ordinary problems of engineering

(*q*) On account of the special character of this equation $F = mA$ it is unfortunate that it should be so often taken as the fundamental equation of dynamics instead of the general equation $F/W = A/g$ from which it is derived (galley 41)

Comments on the above Extracts

(*a*) For "length, time, angle and force," we would better read "space, time, matter and force" Mechanics is the science of the action of force upon matter. Matter is that upon which force acts, and it is just as important as force in most engineering problems Matter occupies space, therefore space is one of the four elementary concepts of mechanics Length is merely the linear measurement of space in one direction, and therefore it should be placed in the list of derived quantities, with area and volume Angle should also be placed in the list of derived quantities, it is the difference in direction of two lines that meet in a point, or the difference in position of a line that is rotated a certain distance about one of its ends

(*b, c*) If "the quantity called mass" is the quantity of matter in a body, then this statement is incorrect The quantity of matter in a body is of the utmost importance to the engineer, independent of the force of gravity acting upon it, if the body is to be moved horizontally, or rotated, or accelerated, or if he or his client has to pay for it

(*d, e*) Here are two definitions of "mass" which are inconsistent If mass is the quantity of matter, why should it be "thought of, roughly"? Why is it not defined with precision as the quantity of matter as determined accurately by weighing it on an even balance scale and compared with the standard pound (or kilogram)?

The second definition is the ratio W/g, or a quantity proportional to this ratio

The fact is that the word "mass," as applied to matter, is used in three different senses

1 As synonymous with "portion," "piece" or "lump" of matter, as in the expression "this mass weighs ten pounds," the words "weighs ten pounds" referring to the quantity of matter as determined by weighing

2. As synonymous with the word "weight" (quantity of matter), as the word weight is universally used in ordinary language, and nine times out of ten by the engineer, who rarely uses the word "mass" in this sense Example: "This lump has a mass of ten pounds."

3. As synonymous with the ratio W/g, where either W is the weight (quantity of matter) and g is 32 174, the acceleration due

to gravity at the sea level at latitude 45°, or W is the force with which gravity attracts the body at any given place and g is the acceleration due to gravity at that place The quantity or ratio W/g is constant in either case In this the mass of the ten-pound lump is 10/32 174, and since it is a ratio it has no unit The statement that "the engineers' unit of mass is 32 2 pounds," found in some books on physics, is *incorrect* The engineer has no such unit

Giving the name "mass" to the ratio W/g was perhaps unfortunate, but it can not now be helped since it is universally used in this sense in the engineering text-books of the past sixty years or more It is a handy term, and the use of the single letter M instead of the fraction W/g often simplifies calculations It is hard enough to get rid of a bad term, for example, "poundal," which has been in the high-school books on physics for the past thirty years in spite of the numerous attacks upon it It is not likely that we can get rid of the term mass, M, in the sense of W/g unless some one invents another and a better name for it

Of course confusion results from the three different meanings given to the same word "mass," but the confusion arises chiefly from its use in the second sense given above, as synonymous with weight (quantity of matter) It is so used in all the books on physics, but as already stated, is rarely so used by engineers It would tend to diminish the confusion if the books on physics mentioned that in engineering "mass" means the ratio W/g, and not the quantity of matter in pounds, thus preparing students for what they will afterwards learn in their engineering studies

(*f*) "The weight, W, of a body, at a given place, is the force that causes it to fall if unsupported"

The word "weight" is used in two senses (1) in the sense given in the above definition, which is that of the text-books on physics, and (2) in the sense of quantity of matter as determined by the common method of weighing it In this sense it is used universally in ordinary literature and in commercial transactions, and nine times out of ten by engineers, in all calculations in which quantity of matter is involved

In this sense W is a constant quantity, in the first sense it is inconstant, varying with the latitude and with the elevation above the sea level

In the second sense, quantity of matter, the word weight was used long before Newton's time It is thus used in the clause of the constitution of the United States that authorizes congress to fix the standard of weights and measures, in acts of congress establishing the Bureau of Weights and Measures, and in acts of the British parliament It is thus used in the King James version of the English Bible "And they shall eat bread by weight" (Ezek 4 16) It is not conceivable that this meaning of the word "weight" can ever go out of use It is in the language of the people and it is there to stay

The beginning of confusion in the minds of students as to the meaning of the words "weight" and "mass" results from the fact that the high-school text-books use the word mass for what is commonly called weight, and attempt to restrict the word weight to mean only the force with which a body is attracted by gravity at a given place

(*g*, *h*) "If the mass of a body is one pound (mass) then its normal weight is one pound (force)"

By mass we here understand quantity of matter, and not the ratio W/g given in definition (*e*)

The "normal weight" (this appears to be a new and useless term, and therefore undesirable) is the force with which a body is attracted to the earth by gravity at latitude 45°.

If the sentence (*g*) were made to read "If the weight of a body is one pound, then the force with which gravity attracts it at the sea level in latitude 45° is one pound," it would be strictly accurate, in harmony with the every-day use of the language, and would avoid the confusion arising from the use of the word "mass" The meaning of the word "weight" in this sentence is not ambiguous

or doubtful It means both that the quantity of matter will balance the standard pound on an equal arm balance, and that the force which gravity exerts on it at latitude 45° is one pound, as indicated by a properly graduated spring balance

(*i*, *j*) If for the words "normal weight" in these two sentences we use simply the word weight, it will express the idea accurately, whether the word means quantity of matter or the force with which gravity would act on the body at latitude 45° The two meanings are synonymous and the two quantities identical The measure of the quantity of matter in a body is the measure of the force with which gravity attracts it at latitude 45°

(*k*) The process of weighing a body on a spring balance, on the other hand, gives the "local weight" of a body The term "local weight" also appears to be new, but as it strictly expresses the idea of the attraction of gravitation on a body at a given locality, and there is no other short term that so clearly expresses it, it may be considered unobjectionable The words "gravity of a body" might properly be used to express the idea, if text-book writers would agree to it, for its value would vary in the same proportion as the earth's gravitational force varies, with the locality.

The sentence (*k*), however, is true only if the spring balance has been graduated with standard weights at latitude 45° If graduated with standard weights at the locality (other than lat 45°) where the weighing is done, it will give the "normal weight," or quantity of matter, just as an even balance would do

(*l*) This sentence is not clear A spring balance graduated, say, at latitude 30°, by hanging on it successively the standard weights, 1, 2, 3, 4, etc, pounds, and marking the deflection shown by each, will show at latitude 30° the weight (quantity of matter) of bodies weighed on it, but if it is desired that the balance should indicate "local weight," then the standard weights hung on it should be increased in the proportion that the attraction of gravitation is less at latitude 30° than at latitude 45°, or in the ratio 32 174 — 32 131, or 1/1 0013 If 1.0013 pounds is hung on the scale it will indicate 1 pound, and 1 pound hung on it will indicate 0 9987 pound, the "local weight" of 1 pound of matter at latitude 30° Spring balances, however, are never used for weighing as accurately as 1 3 parts in 1,000, since for such weighing a microscope would be needed to read the deflections "Local weight" is rarely needed in engineering problems, and if it should be needed it is determined not by weighing on a spring balance but by multiplying the weight (quantity of matter) by the ratio of the value of g at the location to 32 174

(*m*) "Force may be thought of, roughly, as anything of the nature of a push or a pull" Why "roughly"? The definition of force as a push or a pull is as precise as language can make it

(*n*) "$F/W = A/g$ is taken as the fundamental equation" This is only one form of the fundamental equation The fundamental fact in dynamics is that if a force F is exerted constantly for a time T upon a body free to move, whose weight is W, giving it a velocity V (starting from rest when $V=0$) at the end of the time T, then the following equation is true (in the foot-pound-second system of units)

$$FT=(W/g)V,$$

or, if $A=V/T$ then $Fg=WA$, from which the equation $F/W=A/g$ is derived, also if $M=W/g$, then $FT=MV$ and $F=MA$

(*o*) "If in the fundamental equation $F/W=A/g$ we substitute the expression for mass, $m=c(W/g)$, where c is the numerical factor depending on the choice of units, we have $cF=mA$ Any system of units which make $c=1$ in this equation is called an absolute system of units."

The value of c in the foot-pound-second system is given as 32.174, and in the dyne-gramme-second system as 1. In the foot-pound system $m=32.174W/g$.

This is out of harmony with the engineering text-books and with engineering literature

generally, which make $M = W/g$ If students are taught in elementary mechanics that $m = 32.174W/g$ and in engineering that $M = W/g$, the resulting confusion will be as great as that caused by the poundal and the gee-pound

(p) "The equation $F = mA$ will give incorrect results if the forces and masses are given in any but absolute units In particular it should never be used in the ordinary problems of engineering"

The reasoning that leads up to this conclusion would also condemn the use of the time-honored formulæ $FT = MV$ and $FS = 1/2MV^2$

The equation $F = MA$ is given in all engineering text-books that deal with problems in dynamics, and it has been used from time immemorial with English units and with perfect accuracy

(q) "On account of the special character of this equation, $F = MA$, *it is unfortunate that* it should be so often taken as the fundamental equation of dynamics, instead of the general equation $F/W = A/g$ from which it is derived"

As commonly used by engineers the equation $F = MA$ has no more a special character than the equations $FT = MV$ and $FS = 1/2MV^2$ It is just as fundamental as $F/W = A/g$, which as well as $F = MA$ may be derived from $FT = MV$ If in the last equation we take $V/T = A$, then $F = MA$, and if $M = W/g$, then $F/W = A/g$

Whether a certain equation should or should not be used in engineering depends, (1) on its logical correctness, (2) upon its usefulness The three equations $F = MA$, $FT = MV$ and $FS = 1/2MV^2$, are all logically correct, equally in the so-called "absolute" (C G S) system, the pound-foot system, and the kilo gram-centimeter system, provided that in the C G S. system the unit of quantity of matter is the gram and the unit of force is the dyne, or 1/981 of the force with which gravity attracts a gram of matter at latitude 45°; that in the pound-foot system $M = W/32\,2$ and that in the kilogram-centimeter system $M = W/981$, W being the weight of the body in pounds (or kilograms) and the definition of weight being the quantity of matter in a body, or the force with which gravity attracts it at latitude 45° As to the usefulness of the equations, this has never heretofore been doubted They have filled the engineer's need for a set of handy formulæ for accelerated motion, and they are easily understood by the student

More than ten years ago a high-school student in despair over his problems in dynamics, on account of the obscurity of his text-book and of the teacher's explanations, appealed to the writer for assistance He was told to forget the formulæ of the text-book, with its poundals and units of mass and to memorize the following $V = \sqrt{2gh}$, $S = 1/2VT$, $FT = MV$, $F = MA$, $FS = 1/2MV^2$ and $M = W/g$, F being force in pounds, M nothing else than $W/g = W/32\,2$, or $W/32\,174$ (if great precision is needed) (no "concept of mass" needed) and W weight in pounds (quantity of matter as weighed on a platform scale) With these equations the student soon solved every problem in the book that referred to bodies uniformly accelerated Many times since the writer has had occasion to give the same advice, and always with the same result

Here is a simple problem in acceleration, with its solution by the engineer's method and by the method of the committee's report

What is the draw-bar pull required to accelerate a railroad car whose weight is 100,000 pounds, on a level track, in latitude 30°, at the rate of 1 foot per second per second, friction neglected? The engineer's solution $F = MA$, $M = W/g$, $A = (V_1 - V_0) - T$

$F = 100{,}000 - 32\,2 \times 1/1 = 3{,}105\,6$ pounds

The mathematician's solution First look up the value of g for latitude 30°, $= 32\,131$. In latitude 45° $g = 32\,174$ Weight is the force with which gravity attracts a body at a given place The unit of force (pound) is the force with which gravity attracts the standard pound at latitude 45°, where $g = 32\,174$ A weight of 100,000 pounds at latitude 30° is therefore a force of $100{,}000 \times 32.131/32.174$ pounds, $= W$ "The formula $F = MA$ should never be used in the ordinary problems of en-

gineering" Using the formula $F/W = A/g$ we have $F = AW/g$. Since g is to be taken for latitude 30° its value is 32.131. We then have $F = 1/1 \times 100{,}000 \times 32.131/32.174 \times 1/32.131 = 3{,}108.1$ pounds.

If the engineer had used the more precise value of g at latitude 45° he would have obtained the same result as the mathematician. He would not consider that the value of g at latitude 30° entered into the problem at all. In the mathematician's solution it enters twice, in numerator and denominator, and therefore cancels out.

The only cases in which the engineer ever needs to consider the value of g at latitudes other than 45° are those of precise calculations in which the force of gravity at a particular place enters into the problem, as in the case of the velocity of falling bodies, the power of falling water, the value of the mechanical equivalent of heat, etc. Thus the mechanical equivalent of heat is 777.52 foot pounds, or the work of lifting 1 pound 777.52 feet high, at latitude 45°. The figure obtained by experiments made in raising weights at a lower latitude would be greater in the proportion that the attraction of gravity is less. Steam at a temperature of 327.8° F. has a pressure of 100 pounds per square inch above vacuum if the pressure is measured by its lifting a weight (piece of metal) at latitude 45°. It would raise a heavier weight, in the ratio 32.174/32.131, at latitude 30°, and a lever safety valve would have to be loaded with a larger weight at latitude 30° than at latitude 45° to resist the pressure. A bar of metal tested on a lever testing machine at latitude 45° and showing an ultimate resistance of 32,131 pounds would show 32,174 pounds if tested at latitude 30°, since at latitude 30° the poise on the lever would be attracted less by gravity than at latitude 45°, and it would have to be moved farther out on the scale beam to balance the ultimate load applied to the test piece.

Note on "The Concept of Mass" (Galley 35)

It is not clear just what the report means by the word "mass." It is defined in one paragraph as "the ratio W/g, or a quantity proportional to this ratio, $m = c(W/g)$, W here being a force and not a quantity of matter," but a little later appears the expression "the mass of the body measured in units of mass," indicating that by mass is meant quantity of matter.

A great deal of mental energy has been wasted by teachers and text-book writers in trying to give high school and college students a "concept of mass," and more trouble is yet in store for teachers and students if future text-books adopt the language of this report concerning the "concept."

A boy before he goes to the high school has a perfectly clear idea of matter and of weight. He knows that matter is weighed by the grocer on even-arm balances and platform scales, and he has seen meat weighed on spring balances. He knows that in order to answer the question "How much sugar is in that package?" the weight of the package is obtained by weighing it with a balance, using pieces of metal called weights, or by putting it on a spring balance and noting the indication. He knows that the weight of a pound of lead is 1 pound, whether it is weighed in London or in Panama, and that it is bought and sold as a pound everywhere that English weights are used. He has never heard the word "mass" except in its common meaning, of something like "bulk," or as a general term of indefinite quantity, as in the expression in the preface of the report, "lost sight of in a mass of details." When he begins to study physics, however, he has to learn that what he thinks he knows about weight is all wrong, that the weight of a thing is not constant, but variable, varying with the latitude and elevation above sea level, that it is not the measure of quantity of matter, but only of the force with which the earth's gravity attracts matter, that the word "mass" should be used where he formerly used "weight", and that he must get a "concept" of mass different from the concept of weight. Later he learns that mass is also $c(W/g)$, the ratio of the force with which gravity attracts matter at a given place to the acceleration due to gravity at that place, multiplied by a coefficient, c, which has

different values according to which system of units is used, there being six systems, kilogram-centimeter, pound-foot, dyne-centimeter, poundal-foot, G_s-kilogram-centimeter and g_s-pound-foot, that in the first system the value of c is 980.665, in the second, 32.174, and in the other four systems 1, but that the last three are only in the text-books (and students must study them and pass examinations on them) and are never used in practise. He is also told that the engineer has a different unit of mass from the physicist, 32.2 pounds, which is not true.

When the student gets into practical engineering studies he is told to forget all he learned about the "concept of mass" and that he need think of the word "mass" only as a short term to use instead of the ratio W/g, $= M$, without any coefficient, c, that weight, W, has the same meaning that it has in commerce, quantity of matter, and that g in that ratio is always the constant, 32.2 or, to be more precise, 32.174. What then is the use of confusing the young student with so many notions of the "concept of mass" when he has to unlearn them later?

The Definitions that should be in the Text-books

Criticisms of the definitions of mechanical units given in the report of the committee will fail of their proper effect unless other definitions are offered which the committee may possibly consider when the report is revised for final publication. The following definitions are offered for such consideration as they may deserve.

Weight, W. (1) Quantity of matter in a body, as weighed anywhere on an even balance scale with standard weights. (2) The force with which the earth's gravitation attracts a body at the sea level in latitude 45° (or at any place where the acceleration due to gravity is 32.174 feet per second per second).

Unit of Weight. The pound, the quantity of matter in the standard piece of metal preserved in the bureau of standards in London.

Force. That which causes or tends to cause or to change motion. A push or a pull.

The Unit of Force. The pound, the attraction of the earth's gravitation on a pound of matter at the sea level at latitude 45°.

The weight of a body, W, is both the number of pounds of matter it contains and the number of pounds of force with which it is attracted to the earth at latitude 45°. The two numbers are exactly the same and therefore it is unimportant which definition is used in connection with the solving of problems.

Local weight, W_1, the force with which the earth's gravity attracts a body at any given place, measured in units of force. It may be determined by weighing it accurately on a spring balance which has been graduated at latitude 45°, with standard weights, or, more easily, by computation, multiplying the weight, W, by the ratio of the value of g at the given locality to 32.174. W_1 varies with the location of a body. The difference between the weight of a body and the "local weight" at latitude 30° is (32.174/32.131) — 1, or 0.0013 of a pound, for each pound. The difference, 13 pounds in 10,000, is so small that it need not be taken into account in any ordinary engineering calculation, in fact, the "local weight" is practically never used in engineering problems. When it is needed it is found by computation from the value of g at the given locality.

Mass, M. (1) W/g, the ratio of the quantity of matter in a body (or of the attraction of the earth's gravity upon it at latitude 45°) to the acceleration due to gravity at latitude 45° (32.174 feet per second per second). This is the meaning of the word "mass" when it is used in engineering problems. (2) The quantity of matter in a body, identical with W (1) above, what is called weight ordinarily in commerce and in literature. This is the definition used in many text-books on physics, in which "weight" is restricted to mean what is defined as "local weight" above.

In answer to an objection that may be raised to the double definition of W, (1) and (2), that the same word, in science, ought not to be used to express two ideas that are so dif-

ferent as matter and force, it may be said that the two are in reality one definition. Suppose that a piece of metal, the standard pound, is hung on a spring balance. The position of the pointer on the scale is then marked 1 pound. A second piece of metal is substituted for the first, and if it brings the pointer to the same mark we say its weight is 1 pound. The 1-pound mark indicates two things at the same time, viz., that the quantity of matter in the second piece of metal is 1 pound, and that the force with which it is attracted by gravity is 1 pound. The word weight is thus logically and accurately defined by what may appear to be a double definition. No useful purpose is gained by applying another word "mass" to mean one part of this definition; on the contrary, the use of the word "mass" in this sense is the chief cause of all the confusion to which students are subjected in their study of dynamics.

WILLIAM KENT

SPECIAL ARTICLES

A STRENGTH AND ENDURANCE TEST

SOME time ago one of the newspapers in Kankakee, Ill., arranged a strength and endurance test in which the contestants were to walk 10 miles, each carrying on his back a sack of sand weighing 100 pounds. The course was laid out over the city streets around several blocks, and to complete the test a contestant must cover it 12 times. According to the estimate of the county surveyor, the course was 4,320 feet (1,316.7 meters) in length, and the 12 laps fixed upon for the contest would, therefore, give a total of 9 miles and 4,320 feet (15.8 kilometers), or approximately 9⅘ miles, instead of the estimated 10 miles. The contest required about 4 hours, beginning about two o'clock in the afternoon and closing at dark, which would be about six o'clock on a November day. Prizes were offered to all who completed the test, and special prizes of smaller value to all who completed one or more rounds. The contest was a public affair, and was witnessed by a large gathering of people who lined the streets through which the contestants walked. A stand was arranged for the judges, and in every way provision seems to have been made to insure accuracy as regards entries, distance covered by each contestant, and so on.

Forty-eight men entered the contest. Of these 44 finished the first round, 25 the second round, 22 the third, 19 the fourth, 15 the fifth, 13 the sixth, 11 the seventh, 10 the eighth, 9 the ninth and 8 the tenth, while 6 completed the 12 rounds and fulfilled all the conditions of the contest.

The ages of the six successful contestants ranged from 21 to 52 years, four of them being 36 years old or over. Their body weight ranged from 150 to 255 pounds, the average being 189 pounds (86 kilograms). Of the 38 other contestants who completed one lap the ages ranged from 17 to 61 years, the majority being 30 years or over, while eight were over 40 years old. The body weights ranged from 120 to 200, being on an average 162.4 pounds (74 kilograms).

As shown by the account of the contest published in the Kankakee press, each of the six men who completed the course felt that he was in condition to continue for a longer distance, but this the management did not permit.

The men who entered the contest were residents of Kankakee and were of different nationalities, including Germans, Scandinavians, French Canadians, a Pole and a Turk, while, judging by the published list of names, about one third of them were Americans. The newspaper[1] under whose auspices the contest was held published a list of the winners, with names and addresses, and data regarding their age and weight, as well as a general description of the affair.

Through the courtesy of the editor of the paper, and by correspondence with a number of the contestants, including four of the six who completed the contest, additional data were secured, particularly with reference to the dietary habits of the men and their condition as regards training when they entered the contest. A circular letter of inquiry was sent to the successful contestants and to those

[1] *Kankakee Republican*, 1907, November 29, p. 1.

who completed one lap. Of the replies received four were from the successful contestants, and two from the group completing one lap, while one was unsigned and consequently the group to which the writer belonged is uncertain. It has seemed a fair assumption in discussing the results that he belonged to the larger group, that is, those completing one round and not the entire course. The circular letter made inquiry as to the number of meals eaten per day and as to whether the subject considered himself a medium, hearty or light eater, whether he was fond of athletics and kept in training, and whether his usual occupation involved any considerable amount of physical work. To obtain more specific data regarding the food, one of the questions was "Do you use all the ordinary foodstuffs and beverages such as are given in the following list? If there are any which you do not use, please cross them out." The list included bread, cereal foods, butter, milk, cheese, eggs, meat, vegetables, fruit, sugar, tea and coffee.

The majority of those who answered the questions considered themselves hearty eaters, and all habitually took three meals a day. One considered himself a medium hearty and one a light eater, while one did not specify.

As regards the ordinary foods included in the list, the answers received from the contestants show that, making allowance for some individual preferences, all these men lived on a mixed diet composed of the ordinary food materials, and it is probable that those who replied were fair representatives of the whole number participating in the contest. As regards individual peculiarities of diet, three of those who furnished information stated that they did not use cereal breakfast foods, and one that he used them only sparingly. One of the men ate little fruit except apples, and two used no cheese, while two used neither tea nor coffee and one other no tea.

In the case of the four winners of the contest it seems worth while to summarize in somewhat more detail the data furnished.

F. G., who was 24 years old and weighed 120 pounds (54 kilograms), stated that he was fond of athletics, and while enlisted in the Illinois National Guards had military training once a week. He also stated that he walked to and from work, one and a fourth miles, four times daily, and considered that a good deal of physical labor was required in his daily occupation as a shipping clerk in a retail grocery house, as goods had to be looked over, checked and handled, and the various baskets of goods sent out weighed on an average from 5 to 100 pounds. He used all of the foods mentioned but stated that only a little cereal breakfast food was used and that apples were the fruit commonly eaten.

C. H. O., whose age was 40 years and whose weight was 255 pounds (116 kilograms), stated that he used all the foods mentioned in the list, but that as regards vegetables, turnips and cabbage were only used raw, while onions were not eaten at all. He stated further that he had not engaged in any form of athletics since 18 years of age. He believed that his ordinary work involved considerable muscular labor, but further details were not given.

J. B., who was 52 years of age and who weighed 180 pounds (82 kilograms), stated that he did not engage regularly in any athletic exercises, but believed that considerable muscular work was required by his daily occupation. No further details were given on this point. As regards the character of his food, he stated that he used bread, cereal breakfast foods in limited quantity, butter, milk, cheese very sparingly, eggs, meat (mostly salt pork), vegetables, fruit, sugar, and both tea and coffee in limited quantity. A diet in which salt pork is the principal meat, with eggs, bread, fruit and vegetables would seem to resemble more closely than any of the others the diet which was once very characteristic of farms in many localities, but which is less common now than formerly, owing to a greater abundance of ice for keeping fresh foods and to improved methods of transportation and other modern conveniences. J. B., who was the oldest of the successful contestants, believed that he could have carried the load of 100 pounds for 15 miles.

G. H., the remaining successful candidate who supplied data, stated that he was 21 years

old and weighed 150 pounds (68 kilograms) He was not fond of athletics and did not keep in training, though he believed that his usual occupation involved a considerable amount of physical work As regards food, he stated that he used bread, butter, cheese, eggs, meat, fruit and coffee, and that he did not use cereal foods, milk, vegetables, sugar and tea He considered that he ate a medium amount, as distinguished from the other three successful contestants quoted, who stated that they were "hearty eaters."

Judging from the data summarized, it appears that although there were some individual peculiarities in the selection of food, all four of the successful contestants who supplied data used a mixed diet, made up of the ordinary food materials, and the same was true of the other three men who furnished information.

The question of energy expenditure in walking has been exhaustively studied under a variety of conditions by Zuntz and his associates According to the data obtained by Zuntz and Schumburg[8] with soldiers marching on a level, the energy expenditure for motion of forward progression averages 0 52 calorie per kilogram of body weight per 1,000 meters Practically the same figures for energy expended in walking on a level have been reported by Durig,[9] in his study of respiratory quotient and energy expenditure of men marching on a level, at low and high altitudes

When consulted regarding the probable energy expenditure under the conditions of the Kankakee contest, Professor Zuntz stated that he was of the opinion that a special factor should be used for the load carried, and that not less than 0.6 calorie, perhaps even 0 7 calorie, per kilogram of load per 1,000 meters of distance covered would be a proper factor.

Taking into account the above-mentioned values, the calculated average energy expenditure of the six successful contestants would be 1,137 calories, of which 707 would represent the energy expended in moving 86 kilograms, the average body weight, over a distance of 15 8 kilometers, and 430 calories the energy expended in moving over this distance the load which was carried

As regards the individuals who completed the entire course, the calculated energy expenditure for F G, who weighed 54 kilograms, would be 874 calories, of which 444 calories represents the energy expended in moving the body over the course, and 430 calories that for the load The energy expenditure for O. H O, who weighed 116 kilograms, was calculated to be 1,383 calories, of which 953 calories represents the expenditure for the body, and 430 calories that for the load. For J B, who weighed 82 kilograms, the calculated energy expenditure would be 1,104 calories, 674 calories representing the expenditure for the body and 430 calories that for the load G. H. weighed 68 kilograms, and in his case the energy expended in carrying the load over the full course would be 989 calories, of which 559 calories represents the expenditure for the body, and 430 calories the expenditure for the load

In the case of the 38 other men, with an average weight of 73 8 kilograms, who completed one lap in the contest, the calculated energy expenditure would be 84 calories, of which 49 calories represented the energy expended for forward progression of the body, and 35 calories the energy expenditure involved in carrying the load

Thirteen men completed half the course Assuming that their average body weight was the same as the average for all the men who completed one round, namely, 75 kilograms, the calculated average energy expenditure would be 523 calories, of which 308 calories represents the expenditure for moving the body over the course, and 215 calories represents the energy expenditure for moving the load.

Like most towns in the middle west, the streets of Kankakee are comparatively level However, in the account quoted it is stated that there is a grade of about 9 feet per hun-

[8] "Physiologie des Marsches," Berlin, 1901, p 299

[9] *Denkschriften der Mathematisch Naturwissenschaftlichen Klasse der Kaiserlichen Akademie der Wissenschaften*, 86 (1909), pp. 242–291

dred on one of the streets over which a part of the course was laid. This, if it constituted any large part of the whole, would naturally increase the work performed, but apparently the greater part of the course was over streets with very little grade.

Since accurate data regarding the grade of the entire course are not accessible, it has seemed best to compute the results in detail without trying to take it into account. The organizers of the contest were of the opinion that the grade mentioned made the 10-mile course equivalent, in its demands upon the men, to a level course of 15 miles. If such an assumption be made, it would mean an average energy expenditure of 1,706 calories for those who completed the test.

As a result of the Department of Agriculture experiments with the respiration calorimeter, it has been calculated that a man at ordinary work, such as that of a mason or a carpenter, expends in the performance of his daily work, at least 1,200 calories. This means that the average energy expenditure of the man in performing the work of a contest which lasted four hours was greater than the above value for a day's work.

From a single test and so limited data it would be manifestly unfair to draw sweeping deductions regarding the character of the food in its relation to endurance. It is nevertheless a fact that the four successful candidates who furnished data lived on the ordinary mixed diet of the average citizen, and from all the information collected the same was true of all who entered the contest. This contest is of interest on this account and also because the endurance feat undertaken is comparable with the ordinary forms of muscular work which pertain to usual vocations, and so may be fairly considered as furnishing some indication of the fitness of the subjects for successfully engaging in occupations involving manual labor.

The total number completing the trial of strength is small (6 out of 48) in proportion to the total number of entries, but the number (44) of those who carried the 100-pound weight for nearly one mile is large, while it was not until the men had passed the judges' stand four times that the number of contestants dropped below 20.

It seems fair to conclude that the men who engaged in the contest were, as regards their food, their occupation and their general living conditions, representative of the very large group of our population who are living comfortably and meeting their daily obligations in a creditable manner, who are, in fact, living the average life of the average man, with its varied activities and interests.

In so far as the recorded data throw light on the subject, they indicate that the average man living the average life is capable of meeting body demands of considerable severity—a conclusion which perhaps few would question, but which it is interesting to consider in the light of numerical data.

C. F. LANGWORTHY
U. S. DEPARTMENT OF AGRICULTURE,
OFFICE OF EXPERIMENT STATIONS

THE USE OF ACID SOIL FOR RAISING SEEDLINGS OF THE MAYFLOWER, EPIGAEA REPENS

MAYFLOWER or trailing arbutus (*Epigaea repens*), probably the best beloved of all the wild flowers of the eastern United States, is rarely seen in cultivation. It usually does not survive transplanting. No evidence has yet been found that flowering plants have ever actually been raised from the seed.

The development of a system of cultivating the swamp blueberry (*Vaccinium corymbosum*), by the use of acid soils,[1] suggested that a similar method might succeed with trailing arbutus, because the two plants have the same natural habitat, and because a symbiotic root fungus similar to the beneficial and probably indispensable root fungus of the blueberry was found to occur on trailing arbutus.

Seeds were procured in New Hampshire in July, 1909. They were sown in a mixture of kalmia peat, sand, and sphagnum. They germinated in August. After successive trans-

[1] "Experiments in Blueberry Culture," 1910 (Bulletin 193, Bureau of Plant Industry, Department of Agriculture).

plantings in an acid soil consisting of nine parts kalmia peat, by bulk, and one part clean sand, the plants in August, 1910, began to form their flowering buds. The larger plants then more than filled a five-inch pot. They were left outdoors during the winter, were brought into a cool greenhouse in March, and in a few days were in full flower. The plants were remarkably beautiful. The flowers had the characteristic color and fragrance of wild ones and were of unusual size, the largest corolla having a spread of seven eighths of an inch. The foliage was free from insect and other injuries to an extent seldom seen in wild plants.

Plants kept in a greenhouse all winter flowered only sparingly, but they furnished an opportunity for the observation of the fruit. The fruit of trailing arbutus is described in our standard works as a loculicidal capsule, but this description is incorrect, and must have been based on an erroneous deduction from immature specimens or imperfect remnants. The fully mature fruit is not a dry pod. It is as juicy as a strawberry. Its style of dehiscence is not loculicidal, but is that exactly if not melodiously described as "septicidally or rather marginicidally septifragal." In examples of perfect development the wall of the fruit while still green and herbaceous splits along the cell partitions into five valves, which spread backward into a five-pointed rosette, exposing the white, fleshy, succulent interior with the minute brown seeds dotted over its surface. The fleshy part, which looks like an unripe strawberry and is about a quarter of an inch in diameter, consists of the whole interior of the fruit, axis and dissepiments as well as placentæ. These observations as to the character of the fully developed fruit confirm the original observations made in New Hampshire in late July, 1909, at the very end of the fruiting season.

FREDERICK V. COVILLE

SOCIETIES AND ACADEMIES

THE TORREY BOTANICAL CLUB

THE meeting was held at the American Museum of Natural History. The meeting was called to order at 8.15 P.M., with Dr. E. B. Southwick in the chair. Twenty eight persons were present.

The scientific program consisted of a lecture on "Orchids, Wild and Cultivated," by Mr. Geo. V. Nash. The lecture was illustrated by a large number of beautiful lantern slides. An abstract of the lecture prepared by the speaker follows.

By the general public any odd or strange flower was considered an orchid, and as an illustration of this common error nepenthes and bromeliads were cited. The large division of endogenous plants to which the orchids belong was illustrated with a slide of the lily, this being taken as typical. Especial attention was called to the stamens and pistil which are distinct in this flower. As an illustration of a typical orchid flower a slide of *Cattleya* was shown. The uniting of the stamens and pistil into one organ, known as the column, was pointed out as the distinctive character of the orchid.

Another interesting feature is the diversity of the lip form. The lip is one of the petals. In some forms, such as *Odontoglossum*, it much resembles the other petals. In *Oncidium* it is markedly different in size and color, in *Cattleya* it becomes more modified by the inrolling of the base into a tube which surrounds the column, in *Dendrobium* a still greater modification occurs in the inrolling of the margins of the lip into a saccate organ, and in *Cypripedium* this tendency is greatly magnified, giving us the "slipper."

The stem or leaves of orchids are frequently thickened, thus serving as storage organs for water. The water supply of many orchids, on account of the habitat on trees and rocks, is very uncertain, and these thickened leaves or stems carry the plants safely through periods of drought. When the thickened stems are short, and round or oval, they are known as pseudobulbs.

Some orchids grow in the ground and are known as terrestrial. These are commonly found in temperate regions, where dangers from frost exist. The majority, however, are epiphytic, that is, they grow on trees, and are found in warm temperate and tropical regions. The number of species is between 6,000 and 7,000, of which about 150 are found in the United States. The two great centers of their occurrence are in the new world, in northern South America, northward into Central America, and in the West Indies, in the old world, in India and the Malay region. A series of slides was then exhibited illustrating some of the common wild and cultivated forms.

THE SECOND INTERNATIONAL CONVENTION OF THE INTERNATIONAL CATALOGUE OF SCIENTIFIC LITERATURE, LONDON, 1910[1]

BEFORE giving an account of the second International Convention of the International Catalogue of Scientific Literature it will be necessary to briefly review the history of the enterprise and outline its organization. Secretary Henry, of the Smithsonian Institution in 1855, suggested and attempted to establish a Catalogue of Scientific Literature through international cooperation, his efforts, however, were not successful and it was not until the beginning of the publication of the Catalogue of Scientific Papers by the Royal Society in 1882 that his idea was even partly carried into effect. This catalogue continued until 1894 when the Royal Society realized that the task was impossible for any one society or indeed for any one nation to undertake. The Royal Society then through the British Foreign Office called the attention of the governments of the world to the great need of a catalogue of current scientific publications, with the result that an international conference was held in London in 1896 to which twenty-three governments sent delegates, the United States being represented by Dr. John S. Billings and Professor Simon Newcomb. This conference decided that it was both necessary and desirable to begin the publication of a catalogue of scientific literature. Various committees were appointed to consider the numerous questions involved, and a general plan of organization was outlined. A second con-

[1] Read at the general meeting of the American Philosophical Society, Philadelphia, April 20, 1911.

ference was held in London in 1898, Dr Cyrus Adler, of the Smithsonian Institution representing the United States, and a third conference met in 1900 The various plans formulated at these conferences were definitely agreed to and drafts of schedules of classification, the heart of the whole system, were compiled The organization is briefly this all the principal countries of the world, at present numbering thirty-two, undertake to prepare at their own expense a classified index of the current scientific papers published within their domain and to forward the data to a central bureau in London where it is assembled and published in seventeen annual volumes, one for each of the following named subjects Mathematics, mechanics, physics, chemistry, astronomy, meteorology, mineralogy, geology, physical geography, paleontology, general biology, botany, zoology, human anatomy, anthropology, physiology and bacteriology The cost of maintaining the central bureau and of printing the catalogue is defrayed entirely by funds received from the subscribers to the work The regional bureaus are, as a rule, maintained by direct governmental grants The work began with an index of the literature for the year 1901 Supreme control of the catalogue is vested in a body known as the international convention which met in 1905, in 1910, thereafter to meet every ten years This paper is for the purpose of giving an outline of the proceedings of the second convention held in London July 12 and 13, 1910. The event was looked forward to with much interest as the enterprise would then have passed through its formative period and the reports would show to what extent it had become a success. All of the principal countries of the world sent delegates as follows

Austria, Dr. Josef Donabaum (vice-director of the Imperial Royal Court Library, Vienna), *Belgium,* Mons H La Fontaine (director of the International Office of Bibliography, Brussels) and Mons Paul Otlet (secretary-general of the International Office of Bibliography, Brussels), *Denmark,* Dr Martin Knudsen (Copenhagen), *France,* Dr J Deniker (librarian of the Museum of Natural History, Paris), *Germany,* Professor O Uhlworm (director of the German Regional Bureau), *Holland,* Professor D J Korteweg (University of Amsterdam), *India,* Lt-Col D Prain, F R S (director of the Royal Botanic Gardens, Kew) and Mr L H Burkill, *Italy,* Professor R Nasini (University of Pisa) and Cav. E Mancini (Academy of Sciences, Rome), *Japan,* Professor Joji Sakurai (University of Tokyo), *New South Wales,* Professor A Liversidge, F R S, *Russia,* Mons E Heintz (scientific secretary of the Central Physical Observatory, St Petersburg), *South Australia,* Hon A A Kirkpatrick (agent-general for South Australia), *Sweden,* Dr Aksel Andersson (first librarian of the Royal University Library of Uppsala), *United Kingdom,* Sir Archibald Geikie, president Royal Society, Sir Joseph Larmor, secretary Royal Society, and Professor H E Armstrong, F R S, *United States,* Leonard C Gunnell (United States Regional Bureau, Smithsonian Institution)

Mr A B Kempe, treasurer of the Royal Society and Dr P Chalmers Mitchell, member of the Executive Committee, were invited to take part in the convention as was also Dr H Forster Morley, who has since the beginning of the enterprise acted as director of the London Central Bureau.

At the opening meeting held in the rooms of the Royal Society on July 12, Sir Archibald Geikie, president of the Royal Society, was elected chairman and Professor Henry E. Armstrong, fellow of the Royal Society, vice-chairman. Professor

Armstrong is the Nestor of the enterprise and from the beginning of the work has been one of the members of the International Council and chairman of the executive committee Secretaries for the official languages of the catalogue—French, German, Italian and English—were then appointed After an address of welcome by Sir Archibald Geikie and the announcement of a number of hospitable invitations to the delegates, the report of the executive committee was laid before the convention This report formed the basis of most of the discussions that followed and to save repetition its contents will be referred to or quoted in full while reporting the proceedings of the convention

The report stated that the seven annual issues already published had cost the central bureau $257,980, for which $246,410 had been received The size of the first four annual issues had averaged 8,441 pages each, the fifth and sixth issues averaged 10,417 each, the seventh issue contained 9,219 pages The enlargement of the fifth and sixth issues was due to the fact that the various bureaus owing to improved methods had begun indexing journals not previously included in the work When the International Council met in June, 1909, it was decided to use modified titles in the subject index with the result that the seventh issue showed a marked decrease in size and it was estimated that the eighth issue would show an even greater reduction In 1900 it was estimated that the gross income would be $27,500 which it was thought would cover the cost of an edition of 500 copies if each issue comprised not more than 160,000 entries The annual income has been $35,000 while the cost has been $36,855 The increased cost was due to the increased size of the catalogue and also to the fact that a thousand copies instead of five hundred had been printed The working capital needed was larger than originally estimated amounting to a total of $37,500 advanced by the Royal Society on all of which interest is paid It was stated that if the steps already taken were continued the deficit could probably be cancelled, and if the first ten issues could thus be published without loss that in consideration of the extent and difficulty of the enterprise the result would be most satisfactory Foundations having thus been laid for an international organization of great importance and influence it was thought essential that steps be taken to make the existence of the organization better known and its powers of usefulness more fully appreciated

A general discussion of methods looking to reduction of expense then followed taking up among other questions the comparative cost of printing in England and other countries This led to a discussion of the finances of the whole enterprise and the result of the debate may be summed up as follows

That it was necessary to reduce the size of the printed volumes without limiting their usefulness which might be accomplished by revising somewhat the classification schedules so as to reduce the number of cross references and also by abbreviating the references in the subject catalogue Emphasis was laid upon the desirability of consolidating the International Catalogue with other bodies engaged in the preparation of bibliographies of scientific works, thus following a precedent established in 1905 when the Zoological Society of London agreed to cooperate with the International Catalogue in the preparation and publication of the *Zoological Record*. Dr Chalmers Mitchell, secretary of the Zoological Society, on being asked by Sir Archibald Geikie what the saving of expense had been by this fusion of in-

terests replied that the *Zoological Record* when published by the Zoological Society did not pay at all, for it had been prepared by a few zealous specialists who were content with a very small remuneration and the Zoological Society had been willing to bear the expense When the two works were combined in 1905 the Zoological Society did not attempt to reduce the total cost of the *Record* but in fact increased the rate of pay to the compilers He stated that for many reasons it was quite necessary that the fusion should take place, that the combined volume was very much better than the separate publications had been, and that it would have been impossible to keep the *Record* going but for the fusion that had taken place The advantage of amalgamation lay rather in the concentration of effort than in financial saving Sir Archibald Geikie asked if there had been any real difficulties in the combined arrangement, thinking that the fusion was an example of what might be done with other societies As Professor Armstrong and Dr Chalmers Mitchell had been the means of bringing about the consolidation, Dr Chalmers Mitchell's answer is significant He said.

The fusion has taken place, and Professor Armstrong I think will corroborate me in this, we who know the immense difficulties at every stage, know quite well that if the *Zoological Record* could be fused with the International Catalogue Record, then it must be a very easy task to fuse any two other records

The following resolution was then discussed and agreed to

Resolved, That in view of the success already achieved by the International Catalogue of Scientific Literature and the great importance of the objects promoted by it, it is imperative to continue the publication of the Catalogue at least during the period 1911–15 and on recommendation of the International Council during the subsequent five years 1916–20

Following this it was

Resolved, That in view of the resolution arrived at to continue the Catalogue for a further period of five years the Royal Society of London be requested to act as in the past as the publishing body and to make the necessary contracts

Dr Forster Morley was reappointed director of the catalogue and the international convention was authorized to spend annually the sum of $10,000, in addition to the director's salary, for the purpose of carrying on the work of the central bureau

It was then unanimously voted "that it is most desirable that a capital fund should be obtained for the catalogue " It is now apparent that the lack of a capital fund has been the stumbling-block of the undertaking from the beginning Not only has it been necessary to borrow money on which interest must be paid but lack of sufficient income has rendered it impossible to carry out several plans looking to the general improvement of the work Had a capital fund been established in the beginning of the enterprise it would not have been necessary for the subscription price to have been placed at such a high figure, consequently, a larger subscription list could have been expected and a larger edition published at a lower rate to each subscriber No commercial enterprise can exist without sufficient capital and the publication of a great work such as the International Catalogue should not be considered in any other light than as a business enterprise if it is to be regularly continued The subscription cost is $85 per year and experience has shown that if the list could be doubled the cost could be cut almost in half, and if the number of subscribers could be quadrupled a still further reduction in price would be possible A relatively small endowment yielding an annual income of not more than ten thousand dollars to be placed at the disposal of the cen-

tral bureau would render it possible to make many improvements and also to broaden the scope of the catalogue. The sum needed is so small in comparison with the good that could be accomplished that it would be strange indeed if in these days of large endowments some individual can not be found willing to provide the necessary funds. As the idea of the International Catalogue originated in the United States the writer is encouraged to hope that some American will further add to the credit already given to this country by endowing the now organized body with a sufficient fund to properly carry on and extend the work.

At the session of the convention on July 13 methods of administration likely to come before the International Council and the executive committee before the next meeting of the International Convention in 1920 were discussed. Professor Armstrong emphasized the great need of confining the catalogue to references to original contributions to scientific knowledge and of the desirability of constantly consulting specialists in the several sciences regarding the proper classification of the papers indexed. It was thought that the organization could now claim some measure of authority in dealing with questions connected with the bibliography of science and thus bring about greater uniformity in practise. On account of the almost insurmountable difficulties in dealing with the present vast number of journals included in the work of the catalogue it was agreed that a revised list of journals should be prepared to contain only those of recognized scientific importance and that the regional bureaus should agree to index all scientific papers published in these journals early in the year following their publication. The International Catalogue could thus within the year following the appearance of a paper publish a full index of its contents. After much discussion this subject was embodied in the following resolution which was unanimously adopted:

> *Resolved*, That each regional bureau be requested to prepare a list of journals in each science which the Catalogue will completely index in the annual issue following the year of publication and that the central bureau be authorized to publish the lists thus prepared.

The publication of this list does not mean that no other journals are to be considered but the list will consist essentially of journals devoted almost exclusively to scientific matters and these journals will therefore be given precedence in the work of the regional bureaus.

To make it possible to carry out this plan to promptly publish future volumes of the catalogue the following resolution was adopted:

> That the resolution of the year 1900 authorizing the central bureau to close these volumes at different stated dates, each volume to correspond to the literature of a period of twelve months, be confirmed.

The effect of this resolution will be that the separate volumes of the catalogue will not necessarily cover a whole calendar year but will cover a period of twelve months.

Reference was made in the report of the executive committee to a proposed international scheme for the publication of yearly tables of physical-chemical constants and in this connection a communication from Sir William Ramsay was read written in consequence of a resolution passed at the International Association of Academies in Rome to whom an application for patronage had been sent. In the report of the executive committee it was pointed out that this work had been embraced in the original plan for the catalogue and though it was one of great difficulty it was still the intention to publish such tables in connec-

tion with the International Catalogue. It was thereupon voted:

That it be referred to the executive committee, after consultation with the regional bureaus, to consider and decide as to what steps, if any, can be taken for cooperation with the proposed International Commission for the publication of annual Physical Chemical Tables.

The two following resolutions were then agreed to and as each was presented a general discussion of its merits followed. The final decision of the matter can not be better expressed than by quoting the resolutions in full.

The first was,

Resolved, That a committee be appointed to revise the schedules and to make such other alterations as may be necessary in the form of issue of the Catalogue. That it be an instruction to the committee that, so far as possible, the subject index be confined to abbreviated titles and authors' names and numbers to serve as references to the author index. That it be an instruction to the regional bureaus to have in mind constantly the need of maintaining the Catalogue of minimum bulk. That the committee consist of the executive committee and Dr. Deniker, Dr. Heintz and Professor Korteweg.

The executive committee being Professor H. E. Armstrong, Dr. Horace T. Brown, Professor A. Famintzin, Leonard C. Gunnell, Professor H. McLeod, Dr. P. Chalmers Mitchell, Professor R. Nasini, Professor H. Poincaré, Professor O. Uhlworm.

The second resolution was,

That in view of the resolution adopted unanimously by the representatives of the various countries constituting the convention, desiring the Royal Society to continue its responsibility for the publication of the International Catalogue for a further period, the committee appointed be instructed: (1) To take all possible steps to prevent reduplication by the publication of several annual and similar catalogues and indexes on the same subject, by making arrangements such as those now in force with the Zoological Society of London. (2) To obtain further assistance and cooperation in the preparation of the material of the Catalogue from the principal scientific societies and academies and the organizations which collect materials for indexing scientific literature.

The question of the publication of a decennial index referred to in the report of the executive committee was discussed and it was decided that on account of the financial difficulties involved unless the sales of the catalogue increased to a considerable extent the publication of the decennial index could not for the present be entertained. The matter was left for the action of the next meeting of the International Council which would be held within the next two years.

However short the time allotted for this subject may be an account would be incomplete without some mention of the numerous and gracious hospitalities extended to the foreign delegates by the Royal Society, the Royal Society Club and individually by the English members of the convention who lost no opportunity to show their guests every possible courtesy and consideration.

LEONARD C. GUNNELL
SMITHSONIAN INSTITUTION,
April 13, 1911

SOME PRUSSIAN EDUCATIONAL DATA

A MINE of statistical information concerning educational conditions in Prussia is Kunze's "Kalendar fur das hohere Schulwesen Preussens" (Trewendt und Granier, Breslau), which has been issued annually for seventeen years. The 1910 edition has just made its appearance, and the German press is busy rearranging its data and forming conclusions. The interest which Americans in general show in German education warrants some discussion of its information with regard to Prussian secondary schools.

The steady growth in the population of the country is of course accompanied by an increase in the number of secondary schools. In 1900 there were in Prussia, in all, 564

Gymnasien (classical schools) and *Realschulen* (schools with French and English instead of the ancient languages), there are now 725. The city institutions have multiplied more rapidly than those supported by the state. There are now 474 city higher schools as against 251 state schools. In 1900 the figures were 344 and 220. The schools are not increasing in number as rapidly as a few years ago. In 1907, 26 new ones were established, in 1908, 22, in 1909, 12, in 1910, 14.

The practical trend of opinion which instituted the *Realschulen* is still making itself felt. In 1900 there were still 341 *Gymnasien* as against 223 *Realschulen*. Now there are 364 of the former and 301 of the latter. The extreme *Realschule*, however, which offers no Latin at all, is not gaining ground as rapidly as the compromise schools. In 1900 there were 85 *Realgymnasien*, with 138 *Realschulen* and *Oberrealschulen*. Now there are 161 of the former to match 200 of the latter. Here is a faint evidence of reaction against the ultra-practical educational theories of the century's beginning. The *Reformgymnasien*, which begin with a modern language—in all but two cases with French,—in *Sexta* (the lowest of the nine classes) and with Latin in *Untertertia* (the fourth class from the beginning), are increasing in popularity. There are now 110 of them. The *Reformrealgymnasium* in Geestemunde and the one in Osnabruck begin with English instead of French. The regulation *Realschule* offers nine years of French and six of English. There seems no reason for this arrangement except the inertia of French influence. It might be contended that the cultural importance of French warrants great attention to it in the old-line schools but one would scarcely expect such a reason to have much weight with the ultra-practical *Realschulen*.

The line between *Gymnasium* and *Realschule* is not always one of absolute separation. There are numerous *Doppelanstalten*, in which a *Gymnasium* is joined to a *Realgymnasium* or a *Realschule*, and several in which a *Realgymnasium* and a *Realschule* are combined. Some of the regular *Gymnasien* allow students who do not wish to study Greek to substitute a modern language, and there are some instances where *Realgymnasien* and *Realschulen* offer Greek as an elective.

The German secondary schools have never been excessively large. In 1900 there were 60 which had more than 500 students each, in 1910 there are 136. In the former year the Royal Pauline *Gymnasium* in Munster-in-Westphalen and the Guerickeschule in Magdeburg (which was then a *Realschule* and *Realgymnasium* combined), counted 840 scholars each and headed the list. The Guerickeschule lost its *Realgymnasium* and its numerically commanding position, and the school in Munster ceased to grow. The largest Prussian institution is now the city *Gymnasium* and *Realschule* in Mulheim, with 948 boys. If we add the 157 children in the *Vorschule* or preparatory school, who recite in the same building and are under the control of the same director, the school numbers 1,100. The Mulheim school has an average of 31.6 students in a class, its present rival in size, the Royal Berger-Oberrealschule in Posen, with 896 students, has 44.8 in a class.

In 1900 these schools employed 6,860 teachers. In 1910 there are 10,150. The number of officially qualified candidates for these positions decreased considerably during the last decade. In 1895 the number on the waiting list had reached its maximum—1,472. In 1900 it had fallen to 693, and in 1906 to 124. In 1897 there were only 73 unfilled positions in the system. By 1900 the number had increased to 127, and seven years later high-water mark was reached, with 884 vacant places. In the last few years qualified candidates have grown more numerous again. There are now 384, as against 124 in 1906.

Prussian secondary school teachers are generally required to teach two or more subjects. It is interesting to note the equipment of the candidates. One hundred twenty-three are prepared to teach religion and Hebrew, 522 for Latin and Greek, 475 for French and English, 482 for mathematics and physics, 155 for chemistry and natural science, 554 for history and geography, 448 for German, 243 for ath-

letics. Last year's list stood, for the same subjects in the same order, 128, 391, 441, 452, 139, 406, 364, 195. History thus shows the greatest advance, and it is a little surprising to find Latin and Greek coming next. Least popular is religion, and there may be a connection between this fact and the wide-spread criticism of the status of religious instruction in the German schools.

New openings in these schools are not appearing as rapidly as was the case a few years ago. For the last four years the numbers are 355, 323, 286 and 222. Thus the new positions created in 1910 were 133 fewer than in 1907.

The higher schools for girls are, as was to be expected, growing much more rapidly, even though the feminist movement has not taken hold of Germany as vigorously as it has seized some other countries. In 1900 Prussia and her cities were maintaining 104 girls' secondary schools. Last year the number had reached 188, and it is now 225. It will be seen that the rapid increase in the number of these schools is a very recent affair. Twelve of the girls' schools are in charge of lady directors.

There are fifteen regular German secondary schools in other countries, located in Antwerp, Barcelona, Brussels, Belgrano near Buenos-Ayres, Buenos-Ayres itself, Bukharest, Cairo, Constantinople, Genoa, Madrid, Milan, Mexico, Rio de Janeiro, Rome and Tsingtau. Twenty-nine directors and instructors with regular positions in Prussia are at work for the year as exchange teachers or lecturers in other countries.

ROY TEMPLE HOUSE

EDWIN E. HOWELL

ON Easter Sunday Edwin Eugene Howell died at his home in Washington. Geologists, physiographers and educators of our country thereby lost an efficient and appreciated ally.

In the year 1861 the late Henry A. Ward, then professor of geology in the University of Rochester, erected on the college campus a building which he called Cosmos Hall and which was devoted to the assemblage and preparation of scientific material for museums of natural history. The establishment thus instituted grew and developed, and it still flourishes. Its work was performed largely by young men of congenial tastes, who there acquired the practical experience which commended them later to the trustees of larger responsibilities. It thus served incidentally as a training school in the natural sciences and especially in certain branches connected with museums. Among its graduates are Frederic A. Lucas, curator in chief of the Brooklyn Institute Museums, William T. Hornaday, director of the New York Zoological Park, F. C. Baker, curator of the Chicago Academy of Sciences, William M. Wheeler, professor of economic entomology at Harvard University, and Henry L. Ward, director of the Milwaukee Public Museum, and in addition to these the writer, who ranks himself somewhat proudly as senior alumnus. This was Howell's school, his real school despite the fact that the biographies mention only the country schools of his native county and the University of Rochester, which recognized certain special studies by making him a master of arts. He entered it in 1865, at the age of 21, and took his diploma—so to speak—in 1872.

For two years he was a geologist of the Wheeler Survey and then for a year held a similar position in the Powell Survey, his work consisting of geologic reconnaissance in Utah, Nevada, Arizona and New Mexico. Then, having become satisfied that this occupation was not the one for which he was best fitted, he resigned his position and returned to the Rochester Museum, becoming a partner where he had before been an assistant. A few years later he removed to Washington, where he established "The Microcosm," an institution somewhat similar to Ward's Cosmos Hall but devoted more particularly to geologic material and subjects. The modeling of relief maps, in which work he was a pioneer—if not *the* pioneer—for the United States, soon became a specialty, and his monument, for a generation at least, will consist in the plastic representations of physiography, topography and geologic structure which adorn the halls

and walls of museums and schoolrooms throughout the continent

He was one of the founders of the Geological Society of America and was connected with a number of other scientific associations, national and local, but he rarely contributed to their discussions Besides the report on his geologic field work, his contributions to scientific literature included only brief descriptions of meteorites

Personally Howell was quiet, unassuming and sincere His recognized integrity was an important factor in his business success If he had enemies or detractors I have not met them His modeling was not distinguished by its artistic quality, but was realistic whenever the material from which he worked was full His clients found him ever clamorous for facts and anxious to revise work at any stage if it could thus be made more truthful, and his clients, who were numerous among the investigators and teachers of geology and geography, were also his friends

He was born March 12, 1845, in Genesee County, N. Y, and passed his boyhood on a farm In 1880 he married Annie H Williams, an artist His wife died in 1893, but a son and daughter survive him

G K GILBERT

HERMAN KNAPP

THE scant space given in the press to the death of Dr Herman Knapp is but another proof that we have not come to place that value upon great scientists which is characteristic of older countries Had he lived in Berlin or Paris the passing of Dr Knapp would have been one of the great topics of the day, for his was a life of singular usefulness to the community, as well as to the science of ophthalmology, and there were few American medical men who rejoiced in wider renown on the other side of the water than did he He studied at no less than seven European universities He established a dispensary and hospital for eye diseases which is now a part of the University of Heidelberg, at which he taught for four years Settling in this city in 1868, he became at once the foremost practitioner in ophthalmic and aural diseases and the founder of the Ophthalmic and Aural Institute, besides being a professor in the College of Physicians and Surgeons But this is the briefest outline of an enormously busy and useful life Never was there a doctor in New York who gave more generously of his services to the poor and the needy, to them he would go even late at night after an exhausting day's labor, if no other time was available More than that, the whole science of medicine is in his debt for the Archives of Ophthalmology and Otology which he founded, as well as for numerous treatises and text-books of permanent value and for his lasting contributions to the treatment of eye diseases —N Y *Evening Post*

SCIENTIFIC NOTES AND NEWS

DR FREDERIC A LUCAS, curator in chief of the Museum of the Brooklyn Institute, and formerly curator of the U S National Museum, has been elected director of the American Museum of Natural History

DR LEWIS BOSS, director of the Dudley Observatory, Albany, has been elected a corresponding member of the St Petersburg Academy of Sciences

PROFESSOR EDWARD L MARK, director of the Harvard Zoological Laboratory, has been elected a foreign member of the Bohemian Academy of Sciences

DR E B WILSON has been designated Da Costa professor of zoology in Columbia University, succeeding in this chair Professor Henry F Osborn, who becomes research professor of zoology

THE Edward Kempton Adams research fellowship has been awarded by Columbia University to Dr R W Wood, professor of experimental physics at the Johns Hopkins University

A PORTRAIT of Professor John Cleland, who from 1877 to 1909 occupied the chair of anatomy at Glasgow, was presented to the university on April 26 and a copy to Mrs Cleland Before the presentations the senate met and conferred on Professor Cleland the honorary degree of LL D

Dr. Alfred Tozzer, of Harvard University, has been made a corresponding member of the Société des Américanistes de Paris.

President Taft has designated Secretary of Commerce and Labor Nagel and Mr. Chandler P. Anderson, counsellor of the State Department, to confer with representatives of Great Britain, Japan and Russia and to negotiate a treaty for the protection of seals and other mammals in the North Pacific Ocean.

Dr. Issa Tanimura, an honorary fellow in the College of Agriculture of Cornell University, has been appointed by the government of Japan a special commissioner of agriculture to investigate the live-stock industry in this country.

Mr. C. H. T. Townsend has accepted an extension of contract from the Peruvian government, as entomologist of state, to December 31, 1912, and expects to conduct extended parasite work against cotton insects, especially the white scale and the square weevil. A laboratory will be established at Piura, in northern Peru, for the accommodation of the work, and a corps of assistants will be provided.

Dr. L. J. Cole, professor of experimental breeding at the University of Wisconsin, will leave on May 6 for a summer's work in western Europe. His trip will include an inspection tour of all the experiment stations and agricultural colleges.

Professor C. C. Thomas, of the engineering school of the University of Wisconsin, has been appointed the university's delegate to the one hundredth anniversary of the foundation of the University of Breslau, which will be held from August 1 to 3, 1911.

Leave of absence has been granted by the board of trustees of Worcester Polytechnic Institute to Professor Harold B. Smith for a period of two years. About one year will be spent in travel. The second year will be spent in special resident study at Berlin and Zurich, and in the investigation of as many European educational institutions as possible. This leave of absence follows fifteen consecutive years of active work on the part of Professor Smith as head of the electrical engineering department of the institute.

During the Easter recess Professors Gilbert van Ingen and William J. Sinclair led an expedition of Princeton students to Yorktown, Va., for field work on the Miocene formation at that place.

Professor Svante Arrhenius, delivered three lectures at Harvard University on April 25 and 28 and May 1. The titles were "The Mutual Relations of the Exact Sciences", "The Theory of Electrolytic Dissociation," and "Adsorption." A dinner in his honor was given by members of the scientific departments at Harvard on May 3.

Professor E. F. McCampbell, of the department of bacteriology of the Ohio State University, delivered the annual chapter lecture of the Sigma Xi society of that institution on Wednesday evening, April 26, on the subject, "The Poisonous Secretions of Animals."

Dr. George T. Moore, of Washington University, delivered the Sigma Xi address at the University of Missouri on "Modern Botany, its Development and Application."

Lady Kelvin has made a gift of £500 to the University of Glasgow for a prize in memory of the late Lord Kelvin. The prize, which will be accompanied by a gold medal, will be awarded once in three years to a doctor of science whose dissertation contains evidence of distinguished original experimental work.

The freedom of the City of London has been conferred 178 times since the year 1757, the recipients including four scientific men: Edward Jenner, Sir George Airy, Sir Henry Bessemer and Lord Lister.

Dr. Herman Knapp, professor emeritus of ophthalmology in Columbia University, eminent for his contributions to this subject, died on April 30, in his eightieth year.

Dr. Pehr Olsson-Seffer, born in Finland in 1873, formerly instructor in botany at Stanford University, and recently director of the Tezonapa Botanical Station and botanist of the Mexican government, has been murdered by brigands in the Mexican insurrection.

DR CAMERON PIGGOTTY, professor of chemistry in the University of South, died on April 30, aged fifty-five years

MR HENRY SCHERREN, an English writer on zoological subjects, died on April 25

THE death is announced of M Henri Berge, professor of chemistry at the University of Brussels

THE U S Civil Service Commission announces an examination on June 7, to fill one or more vacancies in the position of botanical translator, at $1,400 or $1,500 per annum, in the Bureau of Plant Industry, Department of Agriculture

THE forty-fourth annual meeting of the Canadian Medical Association will be held at Montreal in the first week of June, immediately after the official opening of the new medical buildings of McGill University

Nature states that an important discovery in regard to the existence of man in early Pleistocene or Pliocene strata has been made by the Marquis of Cerralbo in Spain In the alluvial deposits of the River Jalon, which is an affluent of the Guadalquiver, he has discovered very abundant remains of undoubted *Elephas meridionalis* in contact with well-characterized implements of human workmanship of the proto-Chellean type Photographs of the specimens and of the cuttings in which they occur have been received from the marquis in Paris, and Professor Marcelin Boule left Paris in Easter week in order to examine the site and the specimens It is possible that *E. meridionalis* may have survived in the south of Europe from Pliocene into early Pleistocene times, but the association of implements of human workmanship with this early species of elephant is altogether new

OFFICERS of a number of the leading colleges and universities charged with the business administration, met at Yale University on April 27. The following subjects were proposed for discussion

Methods of increasing graduate financial interest in university endowment

The problem of the investment of trust funds—whether to apply each investment to a specific fund, or to invest the funds collectively

Dormitories—their construction, management and the income to be expected from them

What constitutes adequate fire, liability and casualty insurance?

Budget and appropriation systems

The requirement of bonds from students for the payment of college bills

Infirmary administration and sanitary inspection

Pensions for employees and the general question of "welfare work" for employees

The problem of the dining hall

The establishment of central stations for heat, light and power

Consideration of the Carnegie report on "Academic and Industrial Efficiency"

Cooperative purchasing by universities

Should students who can afford it pay the full cost of tuition voluntarily?—about 40 per cent of the cost of education now being paid by the student

"Functional" administration versus "departmental" administration

"Centralized administrative responsibility" versus "committee government"

THE eighth annual session of the Puget Sound Marine Station at Friday Harbor, in the state of Washington, will begin on Monday, June 26, and continue for six weeks, closing on August 5. The laboratory will be under the general charge of Professor Trevor Kincaid, of the University of Washington, assisted by a council representing the several institutions participating in the organization. The instructors with the courses they offer will be as follows *Ecology*, Trevor Kincaid, University of Washington; *Comparative Embryology*, W J Baumgartner, University of Kansas; *Plankton*, John F Bovard, University of Oregon, *General Zoology*, H B Duncanson, State Normal School, Peru, Nebraska; *Algæ*, Geo. B. Rigg, University of Washington; *Phanerogamic Botany*, A R Sweetser, University of Oregon The work of the station entered upon a new phase during the session of 1910, when a substantially constructed three story laboratory was put into commission, provided with running salt and fresh water, electric light, aquarium tanks, etc An addi-

tional building is now under construction. The equipment has been greatly improved through provision for more thorough deep-water dredging operations. Exceptionally fine opportunities are presented for the collection of class material as well as for systematic and ecological study. Information in regard to the station will be supplied by the director, Trevor Kincaid, University of Washington, Seattle, Wash.

The following resolution with reference to the chestnut blight disease was presented by Professor John W. Harshberger at the general meeting of the American Philosophical Society and unanimously adopted on April 22, 1911:

WHEREAS, there has appeared in the eastern United States a destructive fungous disease of the chestnut tree, known as the chestnut blight, which as a disease in epidemic form threatens to destroy the native chestnut throughout North America, be it

Resolved, that the American Philosophical Society in general meeting assembled heartily supports appropriate legislation in Pennsylvania, in other states, or by the national government looking to the eradication of the disease by the establishment of a quarantine, or by other more drastic measures of destroying the diseased trees along the outposts of the infected areas, and be it

Resolved, that the members of the national Congress and the members of the several state legislatures are requested to adopt such legislation, as above mentioned, and appropriate sufficiently large sums of money with the view of stamping out the disease before it reaches the main body of chestnut timber in the southern and southwestern deciduous forests of our country, and it is

Resolved, that the members of the American Philosophical Society will support the movement begun in Pennsylvania looking to the eradication of the disease from our too rapidly disappearing forest areas.

THE London correspondent of the *Journal* of the American Medical Association writes that the National League for Physical Education and Improvement has proposed that the London memorial to the late King Edward, whose great interest in sanitary problems is well known, should take the form of a public health museum. In a recent conference of health-promoting institutions, a discussion on the need of coordination disclosed the existence of over eighty such national agencies in London and of a large number of local agencies in London and throughout the country. It was shown that these suffered much both in finance and work from overlapping, from separation of offices and staff and from lack of coordination. The striking success of the tuberculosis exhibition opened in Dublin and then transferred to the Irish Village in the exhibition at London and to other places throughout the country, demonstrated the great interest taken by the public in sanitary questions. It is proposed to erect a popular museum which should accommodate a permanent collection and also furnish duplicate material for the equipment of traveling vans. It should be a model in constant and close relation with provincial museums to which it would probably give birth. It might also become a loan center for the distribution of replicas of its models and diagrams for circulation among schools and institutions. The building should also form a nucleus for the coordination of the various health-promoting institutions, both metropolitan and national. For this purpose, it should include the following: Two or three meeting halls of different sizes, ten or twelve committee rooms, central offices, a library and reading rooms, lecture rooms, workshop and draftsman's room. The cost of maintenance would be met, to some extent, by the rental of suites of offices, halls, committee rooms, especially by health-promoting conferences and institutions, and to some extent by small fees for courses of instruction. In the main, however, instruction must be given at a low cost, fees being charged only when they will guarantee greater interest in those who pay, and being reduced to such a level as will admit of the greatest possible use of the facilities provided. This would be sufficient grounds for appealing for subscriptions to trades unions, friendly societies, insurance companies and the general public. An appeal will be made for a memorial sum of $500,000 and a subscription of $25,000 a

year as a minimum The early cooperation of organizations of the working classes and of those working for the prevention of tuberculosis and alcoholism will be sought

THE Weather Bureau has published for many years the *Monthly Weather Review*, treating of the general weather conditions throughout the United States as a whole, with occasional summaries of climatic data from other and frequently little known regions of the earth Also there have appeared in its pages many scientific and popular contributions from the best students of meteorology and kindred subjects, thus making it one of the leading meteorological and climatological journals of the world A considerable number of the several monthly and annual issues of this publication have accumulated in the files of the Weather Bureau and it is thought they would be a valuable addition to any library If any library desires copies of these publications, either for the completion of broken files or as new matter of public interest, copies of such issues as are available will be furnished free of charge upon request

UNIVERSITY AND EDUCATIONAL NEWS

COLUMBIA UNIVERSITY has received an anonymous gift of $10,000 annually for four years for surgical research, and a gift of $15,000 for five years for the establishment of a bureau to study legislative drafting

FURMAN UNIVERSITY, the Baptist College of South Carolina, has now in course of construction a $50,000 science building which will accommodate the departments of chemistry, biology and physics with lecture rooms and laboratories Half the cost of this building was supplied by local contributors and the other half was the gift of Mr Rockefeller It is expected that the building will be completed and ready for occupancy at the beginning of the next session, in September

MISS A. H. CRUICKSHANK, daughter of a former professor of mathematics in Aberdeen University, who during her lifetime made generous gifts to the university, has bequeathed £22,000 for the endowment of a chair of astronomy, the establishment of a science library and the provision of law prizes in the university, and the residue of her estate for kindred objects

THE Drapers' Company, London, has granted £6,000 to the Battersea Polytechnic for the erection and equipment of a department of hygiene and physiology

DR HENRY PIKE, of the University of Chicago, has been appointed assistant professor of physiology and Dr Warfield T Longcope, of the University of Pennsylvania, assistant professor of medicine in Columbia University

AT Cornell University Mr F K Richtmyer has been promoted to be assistant professor of physics, Mr C W. Bennett, to be instructor in chemistry, and C K Carpenter to be instructor in experimental engineering

THE following promotions have been made in the department of botany of the University of Chicago Charles J Chamberlain, advanced from assistant professor to associate professor, Henry C Cowles, advanced from assistant professor to associate professor, William J G Land, advanced from instructor to assistant professor, William Crocker, advanced from instructor to assistant professor

DISCUSSION AND CORRESPONDENCE

PHARMACOLOGICAL ACTION OF THE NON-ALCOHOLIC CONSTITUENTS OF ALCOHOLIC BEVERAGES

TO THE EDITOR OF SCIENCE In a recent number of SCIENCE[1] D D Whitney, in an article entitled "The Poisonous Effects of Alcoholic Beverages not Proportional to their Alcoholic Contents," cites the following sentences from my report on the pharmacological action of ethyl alcohol[2]

The more concentrated alcoholic liquors or spirits are, from a practical point of view, the

[1] April 14, 1911, p 587

[2] "A Critical Review of the Pharmacological Action of Ethyl Alcohol, with a Statement of the Relative Toxicity of the Constituents of Alcoholic Beverages," by John J Abel, pp 1–169 in Vol II, "Physiological Aspects of the Liquor Problem," Boston and New York, Houghton, Mifflin & Co, 1903

most toxic of all alcoholic beverages If whiskey or cognac were always to be diluted with water until the percentage of alcohol was brought down to ten per cent, they would be no more toxic than wine of the same strength

He then remarks

These statements would lead one to infer that if the alcoholic content of all beverages was reduced to the same percentage, the toxicity of each beverage would be the same If true, such a conclusion would greatly simplify the method of determining the relative harmfulness of the many kinds of alcoholic beverages

It is easy to give a wrong impression by use of sentences removed from their context Statements that precede and follow may be absolutely necessary to convey an author's true meaning Had Whitney included the whole of the paragraph whose beginning he quotes, he could not have drawn an inference which gives an incorrect impression of my report The rest of the paragraph is as follows:

In fact, a number of French authorities maintain that the finest wines are, in proportion to the amount of alcohol contained in them, more toxic than the brandies The question of the relative toxicity of the various constituents of alcoholic beverages has been narrowed down to a study of the action of the higher alcohols, the ethers and aldehydes as compared with that of ethyl alcohol This point of view is justified for the stronger beverages, such as the liqueurs, brandy, rum, whiskey, etc, and the stronger wines As we have seen, however, a study of the misuse of beer would have also to take account of other factors As these factors have not yet been made the subject of special study, we shall confine ourselves to the by-products found in spirits and wines

Numerous other passages could be cited to show that the word "all" has no place in Whitney's inference On page 23 of the report may be read

The liquor sold in France under the name of absinthe contains all the way from forty seven to eighty per cent of ethyl alcohol and is highly flavored with the aromatic constituents of wormwood, anise, fennel, coriander, calamus aromaticus, hyssop, marjoram, etc, the proportion and selection of these flavors varying with the special variety of the absinthe As long ago as 1865 Lancereux maintained that alcohol is, from a quantitative point of view, the chief poison of absinthe Yet there can be no doubt that if the alcohol were removed from absinthe, its excessive consumption would still wreck the nervous system, because of the presence in large amount of the aromatic constituents enumerated

My report had to deal principally with the effect of the various constituents of alcoholic beverages on the higher animals and man, since the work of the Committee of Fifty concerned itself with the problem of intemperance. The experiments of investigators on the action of the higher alcohols, esters, aldehydes and other by-products of alcoholic beverages were given, as also tables showing the relative killing power of these constituents for higher animals and statements in regard to what was known of their action in chronic alcoholism

From all these studies it was concluded that ethyl alcohol is the *preponderatingly harmful ingredient of alcoholic beverages,* and poisonous enough to account for all the evils of intemperance, an ingredient compared with which the small quantities of higher alcohols, aldehydes, etc, associated with it in alcoholic beverages may be neglected by those who seek to reform those evils. Nevertheless the report furnishes abundant proof that the action of the various by-products or non-alcoholic constituents of these beverages were duly considered so far as the data at hand at that time (1899–1900) were applicable to man and the higher animals In the section of the report dealing with the subject of chronic alcoholism passages like the following may be read.

The two examples that have been cited show how necessary it is to study the behavior of *each*[1] of the by-products in alcoholic drinks when administered by itself over a long period before we can attribute to each its own share of the harmfulness which ensues from the prolonged and excessive use of spirits, wines, etc It is not enough to know the toxic equivalent of an alcohol or of a by-product as measured by the experiments detailed in the preceding section in order to deter-

[1] Italics as in the original.

mine precisely what effects will follow their prolonged administration But experiments on animals involving the daily and prolonged administration of small quantities of *each* of the several higher alcohols which are found to exist in traces in distilled liquors are not as numerous as could be desired

Again in speaking of alcohol as a respiratory stimulant, p 116, it is stated that highly flavored wines, brandy and other alcoholic beverages which contain larger amounts of stimulating esters have a more pronounced action than ethyl alcohol and in numerous passages elsewhere throughout the book it will be found that the pharmacological action of ethyl alcohol is contrasted with that of the by-products of alcoholic beverages On p 10 may be read "In 'pure' wines the various ethers and aldehydes constituting the 'bouquet,' the degree of acidity, the amount of sugar and salts, are of importance, both from a medical and from a hygienic point of view"

A report which aims to show that ethyl alcohol is the chief deleterious agent of alcoholic beverages and the one mainly responsible for the evils of intemperance should not be so quoted that one could infer that it was there stated or implied that the effects of *all such beverages on all living things (including rotifers) is to be measured only by their alcoholic content*

JOHN J ABEL

BALTIMORE,
April 19, 1911

THE APPOINTMENT, PROMOTION AND REMOVAL OF OFFICERS OF INSTRUCTION

THE address by President Van Hise, "The Appointment and Tenure of University Professors," which was printed in SCIENCE on February 17, 1911, is interesting in many ways It shows, in the first place, the prevalence of a strong feeling that there is something unsatisfactory about the way in which the power of appointment and removal is exercised in our universities, and, in the second place, it is noticeable for a tacit acceptance of the common assumption that any objection to the way in which a public trust is administered implies a demand for a change in the machinery by which its administration is effected, and does not, as might more naturally be thought, perhaps only exhibit a desire to see the power that directs the machinery made more intelligent If our cities are badly governed by mayors and councils, the remedy is sought in government by commission or in some other purely mechanical attempt to change the locus of power, instead of in the more laborious and less outwardly promising task of purifying it of selfishness and ignorance, and President Van Hise seems to deal with the question of university government from a similar point of view, although, to be sure, he does so for the most part negatively and by inference rather than positively and directly He is undoubtedly right in his contention that the president is the proper officer to be entrusted with the power of appointment and removal, although many will question his implication that the president's right to this power rests on the fact that he makes wise and courageous use of it He is also right in insisting that removals are necessary when efficiency or usefulness are destroyed by physical, mental or moral weakness; and he is justified in attributing some (but not all) of the opposition of faculties to the presidental power of appointment and removal to their selfish desire for permanent sinecures, but his address implies an attitude on some other points to which exception may be taken

For one thing, he is too sanguine, for he assumes two things that there is considerable reason to doubt He seems to think, first, that the acts of governing boards of universities are always in the interests of the students and the public, and, second, that public condemnation is visited swiftly and certainly on all college presidents who employ the power of removal with even a suggestion of unreasonableness or injustice. That these two assumptions are justified may fairly be called into question

One of the greatest weaknesses of American universities, according to an opinion of wide prevalence, is their governing boards These

bodies, composed for the most part of men without anything but the most superficial knowledge of educational practise, often without liberalizing experiences or any real intellectual training, may afford avenues of approach to funds available for the support of educational activities, but they can take no constructive part in educational work, and therefore their action is most intelligent when it is purely perfunctory, as, fortunately, it is for the most part. This is a very general estimate of the worth of governing boards, and there is evidence to bear out its correctness in President Van Hise's address. He says that governing boards merely consider the question of finances in establishing new chairs, so, we may suppose, that if any faculty should so far forget itself as to imagine that a chair of mendacity was necessary, the average governing board would merely count up its cash and determine by that action alone whether to establish it or not. Of course it will be objected that this is a flippant and incomplete way of stating the situation, and that governing boards limit their direct responsibilities to financial matters, leaving all questions of instruction to the sole decision of the faculty. This answer is unconvincing, however, because it is impossible to consider the financial and the intellectual sides of such questions separately, and because it is not fair that the faculty should have only responsibility and no authority in such matters. The fact that there is a strong feeling that governing boards have much power that they do not use intelligently, and that they exercise much authority without being willing to accept a corresponding degree of responsibility, is probably a stronger reason than the one given by President Van Hise for faculty objection to the interference of outside bodies in the matter of teaching appointments. The remedy for this condition, however, does not lie in changing the functions of the officers who interfere or in abolishing them, but in changing their character so that their action on such matters shall be intelligent. If university governing boards were selected with more discrimination than they are at present, and were therefore able to give intelligent consideration to all the larger questions that confront their institutions, many other problems besides those in connection with the appointment and removal of officers of instruction would be solved, and complaints of appointments due to favoritism and expediency or of flagrantly unjust removals could be dismissed as the cry of irritated incompetence—something that can not be done with many that are now made.

It would be pleasant to be able to believe that the public is sure to reprehend any abuse of the power of appointment or removal, but any one who is familiar with the way in which that power has been exercised in many of our universities will have some difficulty in doing so. The public is likely to take an interest in the case of a man whose removal can be attributed to his political or religious opinions, but where only intellectual fitness and teaching efficiency are involved it shows little interest, unless by some accident the case becomes exploited sensationally. It is very much as it is with the exercise of political power. On certain irregular occasions there is great excitement over the appointment of an incompetent or the removal of an efficient public officer, but as a general thing it is taken as a matter of course that such acts shall be unintelligent and inspired by selfishness oftener than a sense of duty. In SCIENCE for August 19, 1910, Professor A. W. Crawford, of Manitoba University, has a letter calling attention to the fact that the University of Pittsburgh, by faculty changes that involved the removal of two professors, effected a saving of $2,000 a year, but that $1,500 of it was added to the salary of the executive officer who made the removals. If the facts are as stated, it would seem that the University of Pittsburgh would be an especially good place to establish a school of politics, as the performance would do credit to some of our most abused municipal governments. The public, however, does not seem to have been at all disturbed by it, in spite of the fact that a reform wave struck Pittsburgh about the time it was done and several councilmen were indicted.

Another illustration of the way the public takes removals can be found in the case of Brown University A dozen years ago the removal of a man from this institution stirred the whole country The man, however, was the president of the university, he had guided it during the period of its greatest development, was, perhaps, its most distinguished living alumnus, and he was removed for holding opinions that were an issue in national politics at the time Ever since that time, according to common report, the power of removal has been invoked in the same institution with great frequency against less conspicuous men Repeated complaints have been raised of men having been cajoled, crowded or thrust out of the Brown faculty with varying degrees of suddenness and consideration In some cases the men so treated had served the university for many years without being found incompetent or even unworthy of regular promotion—something which in most institutions is regarded as establishing a claim that prevents removal on the ground of natural unfitness In other cases, whatever the justification for removal, the action was accomplished in a way to rob it of all appearance of tact and dignified decision, and yet the public has shown no disposition to visit reprehension on the institution, although, according to President Van Hise, it would be sure to do so under circumstances far less capable of being interpreted as indicating unwise or unjust action

The fact that removals are sometimes necessary does not justify the inference, as President Van Hise implies it does, that every removal made is a just and wise one It is because faculties feel that many are both unwise and unjust that there is so much complaint against the power that makes them, and it is the fact that there is some warrant for this feeling, that gives these complaints their force Even if all removals were justified, however, President Van Hise's address shows that executive officers would not be free from all blame in connection with them He states that the college president usually approves without question all nominations for minor appointments, and that only in the case of promotions or appointments to positions of professorial grade does he give the matter any personal attention He might have added, had it lain within the scope of his paper, that many universities exploit their minor appointments in various ways, and by so doing attract many men into teaching who later on have to be removed It must be admitted that some probation is necessary before the fitness or unfitness of a teacher can be determined, and it may be that a college president's time has too many demands on it to permit him to consider every minor appointment It requires, however, something else besides experience to make a teacher, for some mental equipment and training is necessary on which to superimpose that experience, and it lies within the power of college presidents to insist on the possession of this equipment and this training It is also within the power of college presidents to stop the practise of appointing men to minor teaching positions for no better reason than the fact that they will swell the number of graduate students As to whether a president can reasonably be expected to have time to devote to considering minor appointments, it can only be said that if he has not, it might be well to create officers to relieve him of some of his duties and enable him to do so A travelling press agent might serve the purpose Such an officer could relieve the president of the junketing and of the task of conducting the enthusiasm campaigns that are now deemed necessary to keep a university prominent in the race for numbers and notoriety, and the president could be left free to devote himself to more purely intellectual matters It might even be found that the press agent was unnecessary, and that if college presidents devoted themselves more to their natural responsibilities, the gain in efficiency might prove to be a far more effective advertisement than the most ingenious press agent could ever devise or the most energetic one ever carry out

But if it is not possible to agree with Presi-

dent Van Hise that college presidents should be entrusted with the power of appointment and removal because they invariably use it in the interests of efficiency and justice, it is possible to believe so for other reasons. In the first place, if the president makes the appointments responsibility can be brought home to an individual, whereas, if the faculty made them, it would be distributed among a body of men, and individuals could evade it. Then the president ought to be better able to perceive the needs of the whole institution than the faculty, for the views of faculty members are sure to be narrowed by an inevitable tendency to give undue importance to their own and allied subjects. A still more important reason for the president's making the appointments, however, is the fact that he is not like members of the faculty influenced by a fear of competition. It is natural that professors on whom the task of recommending appointments falls should prefer docile mediocrity to men of ability sufficient to develop into rivals for the positions they hold. Intellectual men are proverbially jealous, and the keenness with which they scent rivalry is remarkable, so it is not to be wondered at that promising men find the gateway to teaching closely guarded against their entrance, and that those who succeed in slipping by soon find their path so obstructed that many of them retire in disgust. This is something for the president to correct. His penetration should be sufficient to detect this practise, his courage, decision and dignity sufficient to suppress it and to replace it by a spirit of earnest emulation between teachers of the same as well as different subjects. Unfortunately college presidents do not seem now to be selected because they possess inspiring moral and intellectual qualities, but, one is often tempted to believe, because they can clothe popular fallacies and meaningless commonplaces in language of seeming profundity, or because they are skilful in a sort of emasculated machiavellism. When the public learns to take its responsibilities to education more seriously, we shall have college governing boards and college presidents who discharge their duties more intelligently, and this in turn will ensure faculties of higher effectiveness, so that the whole machinery will acquire a nicety of adjustment that will enable its various parts to work together without the friction that takes place between them now.

It would seem, then, that President Van Hise is right in saying that the present machinery of education needs no external modifications, but it is impossible to accept his implication that educational results are satisfactory. As a matter of fact, present results are very poor, not only in the matter of appointments and removals, but in a general way as well. The only way to improve them, however, is to render the real guiding power of education—public opinion—more intelligent.

A NEW TRANSLATION OF ARISTOTLE'S "HISTORY OF ANIMALS"[1]

"THE History of Animals," by Aristotle, much as it is referred to by naturalists as well as others, has never appeared until lately in a fitting English dress. At last a translation has been published from the pen of a scholar who combines, to an eminent degree, the principal qualifications necessary for such an undertaking—an adequate knowledge of the Greek language and acquaintance with the Grecian fauna. D'Arcy Wentworth Thompson, professor of natural history in University College, Dundee, is the man to whom we are indebted for the new work. It "has been compiled at various times and at long intervals during very many years" and was so long delayed that we had almost despaired of see-

[1] The works of Aristotle translated into English under the editorship of J. A. Smith, M.A. [etc.], and W. D. Ross, M.A. [etc.], Vol. IV., Historia Animalium by D'Arcy Wentworth Thompson, Oxford, at the Clarendon Press, 1910. 8vo, pp. xv + 486^a–633^a + 151.—$3.40.

ing it in print, but we are glad at length to welcome its appearance.

I

Besides various abortive attempts and fragmentary translations, two completed English versions of the "History of Animals" had been published, one in 1809 by Thomas Taylor and another in 1862 by Richard Creswell. Both works evince not only an inadequate knowledge of Greek, but an extremely imperfect acquaintance with zoology and consequently would very frequently mislead the reader. The following extracts from the three translations will serve to give an idea of the characteristics of the several versions and might be paralleled to an indefinite extent.

APES, etc.

Taylor, p. 48 (II, viii., ix.)

Some animals however have an ambiguous nature, because they partly imitate man and partly quadrupeds, such as apes, the cœbi [a kind of apes] and the cynocephali. But the cœbus has the tail of an ape, and the cynocephali have the same form with apes, except that they are larger and stronger, and they have a more canine face. Their manners also are more savage, and they have teeth more canine and strong.

Creswell, p. 32 (II, v, 1)

Some animals unite in their nature the characteristics of man and quadrupeds, as apes, monkeys and cynocephali. The monkey is an ape with a tail, cynocephali have the same form as apes, but are larger and stronger, and their faces are more like dogs' faces, they are naturally fierce, and their teeth are more like dogs' teeth, and stronger than in other genera.

Thompson, 502ª, lines 16–22.

Some animals share the properties of man and the quadrupeds, as the ape, the monkey and the baboon. The monkey is a tailed ape. The baboon resembles the ape in form, only that it is bigger and stronger, more like a dog in face, and is more savage in its habits, and its teeth are more dog-like and more powerful.

These are versions of the following Greek original copied from Bekker's edition.

Ἔνια δὲ τῶν ζῴων ἐπαμφοτερίζει τὴν φύσιν τῷ τ' ἀνθρώπῳ καὶ τοῖς τετράποσιν, οἷον πίθηκοι καὶ κῆβοι καὶ κυνοκέφαλοι. Ἔστι δ' ὁ μὲν κῆβος πίθηκος ἔχων οὐράν. Καὶ οἱ κυνοκέφαλοι δὲ τὴν αὐτὴν ἔχουσι μορφὴν τοῖς πιθήκοις, πλὴν μείζονές τ' εἰσὶ καὶ ἰσχυρότεροι καὶ τὰ πρόσωπα ἔχοντες κυνοειδέστερα, ἔτι δ' ἀγριώτερά τε τὰ ἤθη καὶ τοὺς ὀδόντας ἔχουσι κυνοειδεστέρους καὶ ἰσχυροτέρους.

A comparison of the several versions with the original shows that Taylor's is quite unreliable, Creswell's is the most literal, and Thompson's correct, free and the most idiomatic from an English point of view.

Taylor has corrupted the word kebos into cœbus, for which there is no justification, and has reversed what Aristotle said as to kebos, the original author declaring that it is a pithekos with a tail.

Creswell's chief fault, in this paragraph, is the omission of the English equivalent for "cynocephali"—baboons; the last four words are uncalled for.

Thompson's is pervaded with a full knowledge of what Aristotle said. He has preferred to change the number in several cases, giving the singular instead of the plural. His use of the word ape (instead of macaque), in common with his predecessors, may mislead many, inasmuch as ape is now so generally restricted to the large, tailless simiids (chimpanzee, gorilla, etc.) that they are involuntarily brought to the mind, to the exclusion of others, by the word. Nevertheless, Professor Thompson may claim perfect justification in the fact that the word originally included the monkeys and that the macaques are still popularly known as apes, the northernmost and typical species being especially called Barbary ape. Some might also prefer to express Aristotle's meaning by a phrase like "Some animals combine in their shape characteristics of man and quadrupeds."

One more example (descriptive of the Greek catfish glanis) will illustrate other weaknesses of the older translators. Book VIII of the "History" is under consideration.

THE GLANIS

Taylor, 325 (VIII, xx.)

. . . the glanis, in consequence of swimming on the surface of the water, is injured by the deadly influence of the dog star, and is laid asleep by very loud thunder. Sometimes, likewise, the carp is affected in this manner, but in a less degree.

But the glanis perishes when struck in shallow water by the serpent called a dragon

Creswell, p 219 (VIII, xx, 12)

the glanis, from its swimming near the surface, appears to be star struck by the dog star, and it is stupefied by loud thunder The carp suffers in the same way, but not so severely The glanis, in shallow water, is often destroyed by the dragon serpent

Thompson, 602[b], lines 22–26

For instance, the sheat fish just before the rising of the Dog star, owing to its swimming near the surface of the water, is liable to sunstroke, and is paralysed by a loud peal of thunder The carp is subject to the same eventualities, but in a lesser degree The sheat fish is destroyed in great quantities in shallow waters by the serpent called the dragon

Taylor and Creswell both attribute remarkable offensive powers to the dog-star instead of considering the reference to it as an index of season[2] The notice about the dragon serpent gives an undue air of mystery and weirdness[3] A water snake may seize a catfish as well as other fishes, but sometimes with a fatal result (The present writer, on one occasion on the shore of the Potomac River near Washington, found a large water snake (*Natrix sipedon*) dead with a catfish's trunk in its mouth but the head outside and the pectoral spines immovably outstretched, one piercing the snake's skin behind the corner of the mouth and the other outside)

Professor Thompson has chosen to use the name sheat-fish as an equivalent of glanis That name has been in limited use for several centuries as the designation of the *Silurus glanis* of Europe and has given trouble to lexicographers For example, in the "Century Dictionary," it is derived "appar < sheat[2], a shote, + fish"[4] It was given by Willughby, in 1686, as the English synonym of the German Shaid or Schaid Schaidfisch is an equivalent in northern Switzerland (round Lake Constance or Bodensee) for the same species and doubtless sheat-fish has been derived from that name The English form, to a very limited extent (as by Arthur Adams in 1854), has been used in a wider sense Inasmuch, however, as glanis is a well-known specific name and the fish so called by Aristotle is quite a different species from the true sheat-fish, adherence to the practise of his predecessors in retaining glanis would be deemed desirable by many

II

Aristotle has been frequently and recently called "the founder of systematic zoology" A very distinguished anatomist (Richard Owen) even claimed that "the Zootoka of Aristotle included the same outwardly diverse but organically similar beings as constitute the Mammalia of modern naturalists" All such claims are baseless In view of the frequency with which they and the like are repeated, however, explanation of the scope of Aristotle's work is in place

A striking example of Aristotle's failure to understand principles of natural classification, and fundamental characteristics of animal groups, is exemplified by his treatment of the group of Selachians This, as now accepted, is a very natural division to which class rank has been assigned by some of the best modern naturalists, but Aristotle has ranked with them the angler or fishing frog (*Lophius*) which is only a slightly modified acanthopterygian fish, he did this merely because it was a flat flabby fish and he approximated it to the torpedo because that also was flat and flabby The fact that he repeatedly asso-

[2] The dog star has been long used as a denominator of time For example, Linnæus in 1741, in his autobiographical sketch, records that in the dog days he reached Rouen, on his way to Stockholm, which he reached in September

[3] The "dragon" of the History of Animals was apparently nothing more than an ordinary snake to which extraordinary habits were attributed by popular belief

[4] *Sheat*[2] is defined "The Shad Wright [Prov Eng]," *Shote*[1] "same as Shot[2]," the trout or grayling, and *Shote*[2] "a young hog, a pig" and "a thriftless, worthless fellow" In the old editions of the great "Greek English Lexicon" by Liddell, Scott and Drisler, *glanis* is defined "a kind of *Shad*" The glanis belongs to a widely distinct order from the shad and trout and is not at all like them

ciated the angler with the rays precludes the idea that the error originated with an editor or copyist Many other cases of misplacement of animals, on account of superficial similarity, which differ fundamentally, might be cited did our limits permit It need only be repeated that Aristotle was not "the founder of systematic zoology" and had little or no appreciation of what is now so termed

The "History of Animals," indeed, is by no means a treatise on systematic zoology, but rather a work on physiology It generally includes nine "books," but a tenth was formerly recognized which is now universally regarded as spurious In general terms, in the first three the parts and regions of "blooded" or vertebrate animals are considered, in the fourth the "bloodless" or invertebrate animals and the senses generally are noticed, in the fifth and sixth generation and breeding habits are described and, in the seventh, especially those of man, the eighth and ninth books treat "of the psychology of animals," including the feeding and general habits These categories are by no means exact, however, and various miscellaneous information is interjected No data are given for the determination of the animals considered except what may be found in scattered places respecting certain characteristics, and many species are only noticed once. It is assumed that the reader will know the animals by the vernacular names of the time

There is nothing like a system of the animal kingdom and the groups are only such as were and still are recognized by people without special knowledge of natural history The only categories of classification are the *genos* (genus) and the *eidos* which correspond almost exactly with kind and species or variety of English and are equally vague and to some extent interchangeable Indeed, as Thompson notes (490^b), Aristotle sometimes "seems to juggle with the terms εἶδος and γένος" The only group designations are those in general use, agreeing with English popular appellatives Aristotle especially names the most comprehensive "genera" or kinds of "blooded" animals in book I (Thompson 490^b 9 and 10) and of "bloodless" animals in book IV. (523^b 4–13), the former are Ornithes (birds), Ichthyes (fishes) and Ketoi (whalekind), the latter are Malakia (cuttlefishes), Malakostraca (soft-shelled shellfishes), Ostrakoderma (true shellfishes) and Entoma (insects) Thus each of the Aristotelian "great genera" has received popular recognition among the English as well as other peoples Aristotle, it is true, says (Thompson, I, 490^b 9–11) "There is another genus of the hard-shell kind, which is called oyster, another of the soft-shell kind, not as yet designated by a single term," which he later (IV, 523^b 5) designated as malakostraka, it does not necessarily follow, however, that Aristotle coined the word for the group, he doubtless took an already existent adjective and used it as a substantive A few minor kinds or combinations are recognized, as cetaceans (ketoi), selachians (selachia), horse kind (lophuri) and cuttlefishes (malakia), but otherwise the animals "are only named as it were one by one, as we say man, lion, stag, horse, dog, and so on" (I, 490^b 34)

About five centuries later Apuleius, in his singular "Apologia" or "Defence," gave a list of collective designations or aggregates of animals, and Aristotle's group names constituted practically all the natural groups or classes of the fourteen recorded (Works of Apuleius, Bohn ed, p 286) Many centuries were destined to roll away before the list was added to Indeed, not until the eighteenth century did any naturalist give name to a class independent of popular recognition Linnæus was the real founder of systematic zoology It is true that he was to some extent anticipated by Ray in the previous century, but Ray did not give nomenclatural expression to his logical concepts

Inasmuch, then, as the *genos* and *eidos* are the only categories which have received distinctive names, they only should be recognized Professor Thompson has done this, but he has used the word "genus" in the same vague manner as Aristotle That designation, however, has been restricted by modern naturalists to a group of closely related species and often to a single species when that

had no known close relations The use of the word in the vague Aristotelian sense, therefore, will mislead or at least divert attention, and there is no good reason why kind should not be employed Oliver Goldsmith, however poor a naturalist, was a master of English and he used that word much as Aristotle did genos Thompson's method, however, is far preferable to another translator of Aristotle Dr Ogle, in his generally praiseworthy version of "Aristotle on the Parts of Animals" (p 142), explains that "The vague use of the term [genos] makes it impossible to translate it invariably by the same English word I have therefore rendered it variously — genus — order — tribe — class — natural group — kind, etc, as seemed most convenient in each separate case" Such practise does not convey what Aristotle said or meant, but what the translator thought he ought to say. Most readers will want to know what Aristotle's ideas were and not the editor's

Another case of usage of a word in a different sense from that current is exemplified by the term malakia, which Professor Thompson has translated by mollusks Inasmuch as the latter word is universally extended by all naturalists to a great branch of the animal kingdom, of which the malakia form but a small and aberrant fraction, we certainly have some cause to demur, cuttlefishes is an exact English equivalent of malakia We would prefer to use the last name with the English synonym after it within parentheses Perhaps others would prefer cephalopods instead

Undoubtedly many will also wish that Professor Thompson had given the Greek names of species rather than their supposed English equivalents or, rather, in connection with such equivalents He has, indeed, done so often, but only because he was ignorant or uncertain of the intent of a name There are probably few readers who would use Aristotle for information about animals, most persons would want to know what names he used for animals and what he said or thought about them. Besides, the greater part of the English-reading people live outside the British Islands and to them such words as adder, angelfish, ant, blackbird, dogfish, grasshopper, lizard, viper and the like may convey a different meaning from that familiar to a native Englishman

III

If Strabo is to be credited, some of the manuscripts of Aristotle were subjected to extraordinary vicissitudes and only resurrected after more than a century's entombment in dark and damp hiding places If such were the case[5] with the "History of Animals," naturally in very many places the ink must have been blurred or sometimes completely obliterated It is told that one Apellicon of Teos attempted the restoration of copy and that various editors of subsequent but early times tried their hands at improvement of the text Naturally, then, the Aristotle we know must be often different from that which originated from the hand of the great stagirite

Many emendations have been also made or proposed by various later commentators on Aristotle and many new ones have been suggested by Professor Thompson Thompson had earned the right, by virtue of his attainments and research, to make such, but some of his predecessors had not A flagrant case of ill-advised alteration has been furnished in connection with the words *skaros* and *sparos*, the names of two very notable fishes

Certain authors have proposed to substitute the word *skaros* for *sparos* when it occurs in Book II (508^b 17),[6] Horace A Hoffman (1892) was misled by the suggestion and became so confused that he was "inclined to think that the names σάργος σκάρος and σπάρος are used indiscriminately," and even failed to recognize the *scarus*, perhaps the most famous

[5] There is internal as well as other evidence that the History of Animals was published (multiplied) during Aristotle's life-time

[6] In this case and the following references the first number in roman refers to the "book" of Aristotle's "History" (II), the second to the page of the Prussian Academy's edition adopted by Thompson (508^b), and the third to the line of the page (17) There is no other or independent pagination for the version

fish of the ancients. There is really no confusion in Aristotle's book and his characterizations of the several fishes are quite apt For instance, according to Hoffman, Aristotle "says the σπάρος (or σκάρος, if we follow the other reading) has many pyloric appendages," [etc] and that the σκάρος "has its stomach shaped exactly like an intestine, seems to ruminate just as the quadrupeds do," [etc], these characters differentiate the two almost as well as a modern ichthyologist would do

But there is certainly often occasion for emendation of the generally accepted text and one striking example is the nomenclature of certain fishes which are provided with cæca to the intestines, it occurs in book II (p 508^b 17) of Thompson's translation Probably Aristotle's manuscript had become blurred and illegible at this place and a copyist had inserted words that looked like those that were indistinct or were of the same length

According to Thompson's version, "Fishes have them [cæca] high up about [round] the stomach, and sometimes numerous, as in the goby, the galeos, the perch, the scorpæna, the citharus, the red mullet, and the sparus" Now, assuming that Aristotle knew what he was writing about, the present text is very corrupt

The goby (κωβιός) has no cæca whatever and consequently the name must have been substituted for some other κολίας may have been the original word and the species indicated (*Scomber colias*) would to an eminent degree fulfil the requisite (having very numerous cæca) for the place

The galeos—"γαλεός or the dog-fish, a selachian"—as Thompson notes—"has no cæca. Sch suggests γαλῆ (cf Ael xv, 11), mod Gk γαλία, *Lota vulgaris*, the burbot" That fish has many cæca and therefore would "fill the bill," but unfortunately there is no recent evidence (in Apostolides, Hoffman, Carus or any other recent author) that the fish or the name occurs in Greece A species that would well answer is the bonito (the *pald* of Aristotle, *Sarda pelamys* of recent systematists), which is next in relationship to the *kolias* and whose intestines had elsewhere (506^b 14, 15) been especially noticed by Aristotle

The perch of Thompson (in this place) is not the river perch but a serranid (*Serranus scriba*) still known in Greece as the πέρκα, which has many cæca

The *citharus* does not fulfil the requisites of the proposition in question and is out of place: the name doubtless has been interpolated, κάνθαρος may have been the original word

The names *chromis* and *korakinos* have been involved with *skiaina* to some extent Thus in book IV (534^a 9, 10) the "Chromis or Sciæna" is reckoned among "fishes the quickest of hearing," but in book VIII (601^b 31) the two names appear for distinct species which suffer "most in severe winters" because they "have a stone in their head, as the chromis, the basse, the sciæna and the braize" Thompson, in a note (IV, 534^a), declares that the chromis was "*Sciæna aquila* (or some closely allied fish) said to be still called *Chro* in Genoa and Marseilles" The *Coracinus* has been variously identified "According to Cuvier and J Muller," it was, says Thompson, "*Chromis castanea* (It *coracino, corbo*, etc), the allied fish from the Nile (Athen *l c* [viii, 312]) being *C niloticus* *Umbrina cirrhosa* and *Corvina nigra* are known as *corvi*, and are said to spawn in brackish water, but these we identify with σκίαινα or χρόμις." Gunther thought that "the *chromis* of the ancients appears to be some sciænoid fish" Investigation of the voluminous literature respecting the species involved and the fishes themselves has led to the following conclusions

The *Skiaina* was probably primarily the *Sciæna umbra* of Linnæus (*Corvina nigra* of Cuvier), known now in Greece as the *skios*, as well as under other names

The *Chromis* was apparently the *Umbrina cirrhosa*, to some extent at the present day confounded with the former under the name skios, umbrina, ombrella, etc

The korakinos, as Cuvier and J Muller believed, may have been the *Chromis chromis* (*Heliastes chromis* of Günther). "The allied

fish from the Nile," referred to the same genus by Cuvier, has for more than half a century been associated with numerous other African fishes in a distinct family (Cichlids) and its generally accepted name now is *Tilapia nilotica* *Coracinus* was, however, long a popular name for it, and the "Coracin fish" of Josephus ("Wars of the Jews," III, 10, 8) was doubtless the same or one of the closely related species

The genera *Sciæna* and *Umbrina* belong to the family of Sciænids and *Chromis* to that of Pomacentrids

Apropos of the sexual relations of the selachians, Aristotle brought together most of the names of the species he knew After specific notices of the *batos* (ray), the *trygon* (sting ray) and the *rhine* (angelfish), in Thompson's version (V, 540^b 17) we have this enumeration "And among cartilaginous fishes are included, besides those already named, the bos, the lamia, the aetos, the narce or torpedo, the fishing-frog, and all the galeodes or sharks and dogfish"

Professor Thompson thinks that the bos is "probably *Notidanus griseus*" and the lamia "one of the greater sharks, *e g*, *Carcharias glaucus*, or *Carcharodon Rondeletii*" Such can scarcely be the case Aristotle generally instinctively approximated like forms and he especially segregated "all the *galeodes*" (*πάντα τὰ γαλεώδη*) Inasmuch as the *bos* and *lamia* head the list of flat selachians, they were doubtless rays

The *bos* (*bous*) was almost certainly the *Mobula edentula*, otherwise named *Cephaloptera* or *Dicerobatis giorna* It is known by analogous names (vaca, vacchietta) along the coasts of France and Italy, and allusion is thereby made to the horn-like headfins (caropteres) which project forwards and forcibly remind the observer of a cow's horns Devil-fish is the name by which kindred forms are known along the American coasts

The *lamia* may have been intended for overgrown individuals of the *bous* known only through exaggerated reports It was possibly interpolated by a later editor

The *aetos* was undoubtedly the eagle ray, *Myliobatis aquila* The name is generally supposed to refer to the widely spread wing-like pectoral fins, but Professor Thompson has "little doubt that the original name, still preserved in Sicily, was *pisci acula*, or ἀκυλέης" It is the wing-like expansion and use of the pectorals that is the most striking characteristic of the eagle rays, the spines they share in common with the sting rays (Dasybatids) Professor Thompson might support his conjecture, however, by the fact that, in America, the eagle rays are to some extent called sting rays in common with the dasybatids

The φύκης (male) or φυκίς (female) is named by Thompson "the little phycis or black goby" (567^b 1 10) or merely phycis (591^b 16, 607^b 20) The fish is thus identified unhesitatingly with the *Gobius niger*, as was done by Apostolides, who followed Cuvier and Nordmann The early writers, however, so identified the phykis merely because it had become known as a nest-maker and no other nest-maker than the goby was known Nevertheless, it is now certain that the Aristotelian fish was not a goby but a labrine It was declared by Speusippus (in Athenæus) to be like a sea-perch (*Serranus*) which the *phykis* is not, it was associated with labrines by Aristotle (607^b 18), and it is still called phykopsaro in Greece It is also now well known that several of the European labrines construct nests, those labrines are much more conspicuous and more like the serranids than are the gobies The *phykis* was therefore identified with a Crenilabrus by Gerbe as early as 1861 and there can be little if any question that it really was a labrine It was indeed considered by Belon, more than three centuries ago (1580), to be one of the fishes now known as *Crenilabri* As Gerbe's fine article is almost unknown, it may be noted here as published in the *Revue et Magasin de Zoologie* for 1864 (pp 255–258, 273–279, 337–340) The nest of a northern species (*Labrus maculatus*) has also been described by J D Matthews in the Fifth Annual Report of the Fishery Board for Scotland (1886-7, pp 245–247)

Among the migratory fishes (IX, 610^b 6, 7) are mentioned "the sarginus, the gar-fish,"

etc Professor Thompson notes that "while $\beta\epsilon\lambda\acute{o}\nu\eta$ in VI, 12, etc, is certainly the pipefish, *Syngnathus*, here it may be assumed to mean *Belone acus*, the garfish Mod Gk $\beta\epsilon\lambda o\nu\acute{\iota}\delta\iota$, $\sigma\alpha\rho\gamma\acute{\alpha}\nu\nu o\varsigma$, $\sigma\alpha\rho\gamma\acute{\omega}\nu\nu o\varsigma$, It aguglia $\sigma\alpha\rho\gamma\hat{\iota}\nu o\varsigma$ and $\beta\epsilon\lambda\acute{o}\nu\eta$ are probably synonymous, and one or other of them is interpolated" But here, as elsewhere in the "History," the *Belone* is undoubtedly the pipefish The garpike and pipefish are both very elongate and have the preocular region extended and consequently are sufficiently alike superficially to contrast with other fishes Assuming, then, that the *belone* is the pipefish, the juxtaposed *sarginos* (not mentioned elsewhere) might be conjectured to be the garfish, the conjecture is sustained by the fact that the garfish in modern Greece and the archipelago bears the names Sargannos and Sargõnnus (as Professor Thompson records), as well as *Sargannos* and *Zargana,* these names are clearly but slight variants of each other as well as from *Sarginos* and the real similarity is scarcely veiled by the vagaries of orthography

In the index, Professor Thompson distributes the references to *belone* under two categories, (1) the pipefish, 567ᵇ, 571ᵃ, (2) the garfish, 506ᵇ, 543ᵇ, 610ᵇ, 616ᵃ As already indicated, we consider all the passages in question to be referable to the pipefish, and that alone

In book IX, Aristotle notices the halcyon or kingfisher and especially the nest, he conjectures that "it is possibly made of the backbones of the" *belone,* which Professor Thompson translates "garfish" In a note he adds "If we ask why of all fishes the $\beta\epsilon\lambda\acute{o}\nu\eta$ is specified, it may be because the backbone of the garfish has a peculiar green colour" The Grecian kingfisher, as Aristotle says, "is not much larger than the sparrow," and the garfish is a comparatively large animal and difficult to catch, on the other hand, pipefishes are small, readily obtainable in the vegetation near the shore, and the partly desquamated bodies are easily identifiable

The question of the nomenclature of the *belone* and *sarginos* has been fully considered in an article "On the Families of Synentognathous Fishes and their Nomenclature" in the *Proceedings* of the United States National Museum (1895, pp 167–178) To this reference may be made for further details

IV

Here we must bring our already too lengthy review to a close, although many other passages had been marked for comment or praise The review has been mostly confined to one class because representatives of that class have been most misunderstood and many species erroneously identified Professor Thompson's acquaintance with other classes has been greater and he had some years ago published an excellent book on Greek birds

The new "History of Animals" deserves further commendation on account of its dress as well as contents It is printed in excellent form, as would be expected, having come from the Clarendon Press A new feature, so far as English editions are concerned, is the illustration of various passages by apt and clear figures (eleven in number) explanatory of the Greek text which is subjoined There are remarkably few typographical errors Such are inevitable, however, in a work of its magnitude, and among them are the transposition of the figures 1 and 2 in explanation of the illustration of *Squilla mantis* (525ᵇ), 185 instead of 1856 (568ᵃ note), and *mormirus* in place of *mormyrus* (570ᵇ note) There is one other lapsus to which attention may be called because it is so often made by other writers

Professor Thompson has been misled several times by a French custom of individuals or families adding agnomina to their names The distinguished publicist and translator into French of Aristotle's works, Jules Barthélemy Saint-Hilaire, and the great French naturalists, E and I Geoffroy Saint-Hilaire,[7] are all referred to only under their agnomina In conversation and "for short" the agnomen would be generally dropped, Barthélemy only being used for one and Geoffroy for the other Thus Cuvier, once the intimate associate of

[7] The "G St Hilaire" of p 612ᵃ (note) was Étienne Geoffroy Saint Hilaire (father) and that of p 631ᵇ Isidore Geoffroy Saint Hilaire (son)

Isidore's father and later his antagonist, almost always referred to Étienne Geoffroy St. Hilaire as "M. Geoffroy." In bibliographies and catalogues the respective names are to be found under Barthélemy and Geoffroy.

These are certainly very few and really unimportant blemishes to a work of such general excellence. Before the appearance of the volume, the English-reading peoples were far behind the French and Germans in versions of the "History of Animals." Now we are ahead of all and it will probably be long before it can be superseded by another. Before such shall be the case, the fauna of Greece must be thoroughly explored and doubtless in some sheltered nooks names of animals that have perished in places investigated may be still found in use as in Aristotle's time but under variant modifications. Meanwhile, we shall have reason to congratulate ourselves on the superiority of that which we have.

THEO. GILL

NOTES ON METEOROLOGY AND CLIMATOLOGY

THOUGH authorities agree that climate is practically unchangeable, except when geological time-units are considered, this problem, and especially the corollary relating to mild winters and severe springs, has aroused considerable discussion. The backwardness of spring during the last few years in many parts of the United States has caused considerable alarm among those who are directly affected. In Missouri orchardists have begun to question the policy of continuing the attempt to raise fruit on an extensive commercial scale. In view of these facts, Mr. George Reeder, section director of the United States Weather Bureau, made a study of the cause of the alarm. His investigation has been summarized in a paper, "Late Spring Frosts in Relation to the Fruit Crop of Missouri," which was read at the January meeting of the Missouri State Horticultural Society. It is reprinted in part in the *Monthly Weather Review* for December, 1910. He points out the fact that the daily minimum temperature, rather than the mean temperature for the day, is the important factor, for it is the extreme minimum rather than the mean daily temperature that affects vegetation most. As far as minimum temperatures are concerned, the springs of the last ten years, and particularly the last five years, averaged colder than those of the preceding fifteen years. Not only is the average of the daily minimum temperatures for April and May lower in the last decade than in the preceding two decades, but the frequency of freezing temperatures during these months has been greater of late than formerly. While this is an apparent substantiation of the popular notion that "our climate has changed," he cautions the reader from drawing such a conclusion, suggesting that these changes occur in cycles or oscillations. Data for a sufficiently long period are not available for determining the lengths of these cycles, or for forecasting a change in the present conditions. In conclusion he says, "The popular idea that the climate is changing is evidently an old one, and is caused by the temperature and precipitation conditions remaining for comparatively short periods below or above the normal conditions, such changes should be referred to as oscillations in the weather rather than as changes in the climate."

"The Practical Application of Meteorology to Aeronautics," a paper which was read by the author, Mr. W. H. Dines, before the Aeronautical Society of Great Britain, appears in the *Aeronautical Journal* for January. He showed that the density, the temperature and especially the motion of the atmosphere are of considerable importance to the aviator. The decrease in density of the air with height results in a loss in supporting power, but since the actual resistance to forward motion becomes less, greater speed is possible. The decrease of temperature with height renders it necessary for the aviator to wear thicker and therefore heavier clothing. However, by far the most important consideration in this connection is the wind, both in respect to velocity and to direction. Wind affects aviation in two ways, (1) by its actual presence, and (2) by its steadiness or gustiness. From data obtained by means of kites and balloons, certain

principles have been recognized For example, if one knows the barometric gradient at the ground he can compute approximately the velocity of the wind for moderate heights with the aid of Ferrel's formula and the known rate of increase of velocity with height Moreover, the change of wind direction with height can be foretold when one's position with respect to the barometric distribution is known Such information is of value both to the aeronaut, who in the free balloon seeks a desirable current by ascending or by descending, and to the aviator, who in an aeroplane can travel more advantageously with the wind than against it In the opinion of Mr Dines, progress in the art of mechanical flight depends largely upon meeting and overcoming the difficulty of the gustiness of the wind Many accidents have had their origin in this condition, which is always present in a more or less degree When it is serious enough to render flying hazardous the professional aviator aptly says that the air is "full of holes" In various ways it has been determined that the wind becomes steadier with increasing height, except within the stratum of fracto-cumulus clouds, when they are present Increased speed does not result in increased stability unless the construction of the aeroplane is proportionately strengthened These, and other facts based upon the meteorological data of Blue Hill Observatory are shown graphically, as well as verbally, in a book called "Charts of the Atmosphere for Aeronauts and Aviators," which is now in the hands of the publisher, John Wiley and Son, of New York.

A TEMPERATURE model, the second of its kind,[1] has recently been completed by Mr Eugene Van Cleef, of Chicago. Based upon the data for the period 1890 to 1910, inclusive, it shows in relief the average hourly temperatures for that city Of plaster-of-paris construction, it is two feet long and one foot wide Vertical lines at inch intervals are drawn upon the two narrow sides to represent the months of the year, while similar lines drawn upon the other two sides represent the twenty-four hours of the day The vertical dimension of each point upon the upper surface of the model represents temperature, each sixteenth of an inch representing one degree, the base being zero degrees Fahrenheit The upper surface is anticlinal, and is colored to show the four seasons of the year The model is instructive in many ways, the more striking features shown consisting of (1) the diurnal periodicity of temperature, (2) the change in the occurrence of the daily minimum temperature from about 6 A M during winter to 4 30 A M in summer, (3) the change in the occurrence of the maximum temperature of the day from about 3 P M in winter to about 1 P M in summer, and (4) the more rapid increase of temperature from spring to summer than the decrease from autumn to winter

[1] See SCIENCE, Vol. XXXI., No 807, p 954

IN the neglected field of phenological climatology a noteworthy contribution has been made by Dr E. Vanderlinden in his "Etude sur les phénomènes Périodiques de la Végétation dans leurs Rapports avec la Variations climatiques" The latter describes the results of a study of the relation between climate and the flowering-date of thirty-nine plants, as observed at the Royal Observatory gardens in the suburbs of Brussels, during the fourteen years, 1896 to 1909, inclusive Though the observer was the same throughout the period, all of the plants were not observed each year. The first appearance of the stamens was taken as a basis, since leaves and seeds develop irregularly When possible, artificial conditions were produced to verify conclusions based upon the observations of the effects of similar natural conditions The effect upon the flowering date of a plant by departures from the mean of the various meteorological elements affecting its growth was the real object of the study Rainfall and atmospheric humidity had less effect in this respect than is generally supposed to be the case Radiation, too, especially during the spring months, is comparatively unimportant By far the most effective factor in determining the time of florescence is the temperature, though its importance varies with the different stages of the plant's life. Varieties accustomed to mature at about the same time are affected

similarly by departures in the average weather conditions Though the approximate date of flowering is determined by heredity, the weather conditions of the preceding season, when the seeds are maturing, have no effect When the flowering stage is delayed because of unfavorable conditions, a change to more favorable weather will bring out the flowers with a less amount of "accumulated temperature" than otherwise In general, Dr Vanderlinden concludes that temperature and insolation outweigh all other climatic factors in the development of the plant up to florescence

Having been successful in the recovery of sounding-balloons previously sent up at Omaha, Neb, the United States Weather Bureau again used this station as a base of operations in a series of daily ascensions from February 7 to March 3 As it is necessary to recover the instrument carried by this form of balloon in order to get the desired record, the starting point must be well inland, as the prevailing wind aloft invariably blows the balloons eastward At Mount Weather Observatory, which is unsuitably located for this particular work, pilot balloons have been used since March 1 to supplement the kite flights on the days set apart for international cooperation in aerological exploration No attempt is made to recover these balloons, as they carry no instruments By observing them with transit-instruments until they disappear, the velocity and the direction of the wind are obtained They have been used successfully for this purpose at Blue Hill Observatory since 1909

Though it has generally been supposed that the rain gauge was invented by Castelli in the early part of the seventeenth century, recent discoveries seem to indicate that it was in use in Korea at a much earlier date In Volume I. of the "Scientific Memoirs of the Korean Meteorological Observatory," Dr Y Wada, the director of the newly established weather service of that country, states that in 1442 King Sejo had a cylindrical bronze gauge, about 12 inches high and 5 inches in diameter, in which the depth of the water was measured after each occurrence of precipitation In one which he has found, the cylinder stood in a depression in a boulder upon the sides of which an inscription gave the year and stated the purpose of the gauge Though similar instruments were later used in other parts of the same country, Dr Wada has been unable to recover any of the records, which were doubtless preserved for a time The latter would be exceedingly interesting and valuable at present in furnishing data concerning climatic changes Korea is a land of deficient rainfall now, and the special efforts made to measure it five centuries ago would seem to indicate that it was an important factor in the welfare of the people even at that early date, suggesting similar conditions then

"Dynamic Meteorology and Hydrography," by Professor V Bjerknes, of the University of Christiania, and various collaborators, has recently been published by the Carnegie Institution of Washington The greater part of the volume consists of exhaustive discussions, in nine chapters, of the more important problems in statics Diagrams, tables and mathematical demonstrations are generously employed to make clear some of the complex problems treated The remainder of the book consists of hydrographic and meteorological tables On account of the abstruse nature of the matters discussed, not many will appreciate the value of the work, but advanced students will doubtless find it a notable contribution

Two interesting discussions of the cold of winter anticyclones are found in *Symons's Meteorological Magazine* In the March number Mr W H Dines states that according to the Greenwich records for the fifty years, 1841 to 1890, inclusive, a considerably larger number of days of frost occurred when the mean barometric pressure was below 29 80 inches than when it was above 30 20 inches During that period nearly every frost noted for severity or length occurred in the low pressure series. The statement concerning the supposed cold in winter anticyclones in many text-books he says is not substantiated by evidence, and he suggests that the idea "may

have come from the mistaken notion that an anticyclone brought down air from the upper strata, and therefore ought to be cold. The descending air does occur, but the temperature during an anticyclone a few hundred feet high is unduly warm." In the April number Dr. J. Hann points out the fact that it is not the absolute height of the barometer that is determinative in locating anticyclones, but rather the relative height of the barometer compared with that of the surrounding districts. He maintains that the center of an anticyclonic area is cold in winter, "a focus of cold"—an opinion supported by the investigations of Hildebrandsson on temperatures in cyclones and anticyclones. "The cold arises in winter in anticyclonic regions as a result of radiation favored, in a high degree, by the clear skies and the dry air of the anticyclonic center. One can say definitely that the cooling of the earth in the winter half-year is accomplished mainly in the anticyclonic areas of the land surface. Nocturnal radiation is very intense in the dry air, especially when the surface of the ground is covered with snow." The extremes of the winter months in central Europe show no constant relation to the variations of pressure in central Europe itself, as the "focus of cold" is usually at the center of a persistent continental anticyclone to the northeast. Only in exceptional cases is central Europe itself the seat of this center, and when it is, abnormally cold weather is experienced. As the British Isles usually remain on the western side of the European anticyclone, and thus have southerly and southeasterly winds with high barometer, it follows that high temperatures quite often accompany the high barometer. At the same time, however, it is cold on the continent in the center of the European anticyclone.

THE SOIL, A LIVING THING

FOR many years the fertility of the soil was sought in the chemical substances which analysis proved to be essential to plants and which could be exhausted from the soil by the continual growth of a single crop upon it. To restore the fertility of the soil, it was necessary only to restore the ingredients necessary to keep a plant in a productive condition. Fertilizers were applied which were known to contain the most important materials of plant food and in an available form. Even to-day, there are opposing camps of plant physiologists. One set holds to the principles, first clearly enunciated by Liebig, that the chemical condition of the soil is the most influential factor in the productivity of the garden, or farm. The other group consider that the physical condition of the soil influences the tilth. This school teaches that all agricultural soils contain sufficient quantities of the essential mineral plant foods for many years to come. Recently a more advanced position has been taken by some students of the soil, when they claim that the loss of fertility of many long cropped soils is due to the accumulation of toxic bodies, the accumulated excreta of plants that may have been grown without proper rotation. The true theory of soil fertility will probably be found to be one which will combine all of these theories with another one, which I believe must also be considered in reaching a satisfactory conclusion as to the relation existing between crops and the soil in which they grow.

The theory is one which considers that the soil is a living thing apart from its chemical or physical structure, that in the reaction between the living soil and the growing plant is the true explanation of soil fertility. A fertile soil is a live one. An infertile soil is a dead one. Contrast the soil which is filled with organic matter (humus) and in which numberless fungous, bacterial and protozoan organisms are at work with a mass of clay or sand without such organic material and associated living organisms. The one soil is fertile, because the organisms in the soil react favorably upon each other, the other soil is infertile, because the organisms present in this soil are antagonistic. Recent investiga-

tion has pointed the way along which future research on soils must proceed and some of this instructive work may be reviewed here briefly and in a sequence which suggests the orderly manner in which effect follows cause.

Harter[1] in a paper entitled the "Starch Content of Leaves dropped in Autumn" has shown that the well-established belief that autumn leaves contain very little carbohydrate in the form of starch and sugar is erroneous, for during the summer of 1909, he undertook to trace the change taking place in the amount of starch formed in the leaves of *Liquidambar styraciflua* at different periods, viz., August 17, September 15, October 23 and October 28. On October 28, the leaves were collected which had fallen recently from the tree. The starch in the leaves collected at the different dates was determined quantitatively and was found to be as follows: August 17, 10.91 per cent.; September 15, 10.33 per cent.; October 23, 11.47 per cent. and October 28, 10.79 per cent., based on the dry weight of the material. Since so much starch was found in the fallen leaves of the sweet gum similar material was collected from several other plants and the starch determined as above. The amount of substances in the leaves capable of reducing the copper in Fehling's solution, as determined by the above method, are shown in the table:

	Per Cent
Liquidambar styraciflua	10.79
Gingko biloba	6.32
Platanus orientalis	11.84
Platanus occidentalis	9.89
Styrax americana	5.91
Magnolia obovata	7.19
Quercus pedunculata	14.54
Elæagnus umbellata	10.24

The thought suggested to me after reading the results of Harter's work was one which considered the final disposition of the starch in the fallen leaves. Is this starch disintegrated, or is it changed into a form by which it can be utilized by the roots of forest plants and by the organisms of the soil? To answer this question, I would call attention to the studies of a graduate student of mine, who in a recent piece of work on "Bacteria and other Fungi in Relation to the Soil" has discovered the ultimate destiny of this carbohydrate material. Dr. Rivas[2] by a detailed analysis of the bacterial content of virgin forest soils has shown that the largest number of bacteria are found during October, and the least number during the winter months. He finds that the forest soils contain bacteria which produce enzymes capable of fermenting the carbohydrates, as shown in the following tabulation of his results, which shows the relative proportion of the different ferments produced by the species isolated:

	Per Cent
1. Diastatic ferment acting on starch, found in 24 cultures	60.0
2. Inverting ferments, inverting starch or saccharose into glucose found in 29 cultures	72.5
(A) Inverting starch into glucose found in 22 cultures	55.0
(B) Inverting saccharose into glucose found in 14 cultures	35.5

The presence of these organisms in the soil clearly points to the fact not previously considered in the study of forest soils, that the starch found in autumn leaves can be converted directly by such soil organisms into glucose, and it is probable that this sugar is directly absorbed by the roots of higher plants (a fact not previously suspected), either by the root hairs, or by means of the mycorhiza found abundantly on the roots of many forest trees. Such sugar is also utilized by non-chlorophylless plants, saprophytic fungi (*Agaricus*), and flowering plants (*Monotropa*), for it has long been known these plants can absorb the whole of their organic food (including the soluble carbohydrates) from the humus and that the various mycorhiza living in commensalism with the roots of phanerogams are probably of considerable importance in render-

[1] *The Plant World*, 13: 144–147, June, 1910.

[2] "Contributions from the Botanical Laboratory of the University of Pennsylvania," III., 243–274.

ing the humus available. Saida[3] has shown that the parasitic fungus *Phoma betæ* can fix nitrogen in the presence of cane sugar, as follows:

Substances Added to a Nutrient Salt Solution	Cane Sugar in Grams	Fixation of N in Milligrams
Cane sugar	5	.7393
Cane sugar	17	1.1828
Cane sugar (+ $(NH_4)_2CO_3$ trace)	5	1.1828
Cane sugar (+ $(NH_4)_2CO_3$ trace)	10	1.7742
Cane sugar (+ $(NH_4)_2CO_3$ trace)	20	3.5184
Cane sugar (+ $(NH_4)_2CO_3$ trace)	30	6.2097

More recently Ternetz[4] has isolated five endophytic mycorhizal fungi from certain Ericaceæ, all of which have been found to belong to the genus *Phoma*. Three of these organisms, *Phoma radicis oxycocci*, *Phoma radicis vaccinii* and *Phoma radicis andromedæ*, have shown a well-developed capacity for nitrogen fixation in culture, these three mentioned working even more economically than *Azotobacter chroococcum*, the amount of nitrogen fixation in milligrams per gram of dextrose being under the conditions of culture, respectively 22.14, 18.08, 10.92 and 10.66 for the four organisms mentioned.

With these discoveries in view, we can briefly summarize. The starch in fallen autumn leaves is converted by certain forest soil bacteria into glucose. This glucose is utilized directly by the roots of forest trees, by various saprophytic plants and by the mycorhiza, which by the aid of the glucose are enabled to fix considerable amounts of nitrogen. That the soil is the seat of other activities of as much importance to growing plants, as the above, is proved by the presence of the nitrifying and denitrifying bacteria, of the bacteria that produce the root nodules of the Leguminosæ, of such organisms as *Clostridium pastorianum*, *Bacillus mycoides*, *B. ellenbachensis*, *Azotobacter chroococcum*, *A. Vinelandii* and the hyphæ of numerous saprophytic fungi, various putrefactive bacteria, which perform their rôle in making the soil the fit habitation of the higher flowering plants, producing the tilth or "Bodengare" of the Germans. So too earthworms, insect larvæ, ants and burrowing animals assist in the task of aerating and mixing the surface layers of the soil. It is also evident that the production of toxic excretions by the roots of plants is undoubtedly a factor of importance in soil fertility. Following out a clue which the partial sterilization of the soil by chemicals or by steam gave, it was discovered that the bacteria which are useful in ammonia-making increased four-fold after such treatment, suggesting the presence in the soil of some agent which held them in check. After much painstaking study it was discovered[5] that the soil contained a living protozoon (*Pleurotricha*), which preyed upon the useful organisms, and that the heat and chemicals either destroyed these larger unicellular animals, or inhibited their activity. It can be said, therefore, that the fertility of the soil is largely a biological one, as well as dependent upon the physical, chemical and toxic condition of the surface layers. That the productivity of some soils is due to biological rather than to physical and chemical characteristics is illustrated by the attempts made to reforest Denmark. The peninsula of Jutland was covered originally by forests, but these were destroyed, until by the year 1500 the country had been transformed into a barren heath and sand dunes. At various times attempts were made to reforest these heaths but the results were disappointing until Col. E. Delgar[6] solved the problem. Spruce trees (*Picea alba*, *P. excelsa*), if planted alone did not thrive, but became sickly. The cause of this irregularity in the growth of spruce was thought to be local conditions of the soil, but scientific investigation of such soils did not reveal any

difference in the physical or chemical composition of the soil. It was found, however, that the mountain pine (*Pinus montana*) acted as a nurse to spruce trees planted in its vicinity. In the same soil where spruce if planted alone would remain backward, it would if planted close to a mountain pine grow up vigorously. After some years of trial, it was found that the pine would hamper the growth of the spruce, and so it was cut down at an early age. It was discovered then that even if the mountain pine was cut down at an early age, it imparted to the adjacent spruce trees the ability to grow. The phenomenon is not understood, but it is supposed that the roots of the mountain pine are inhabited by some mycorhiza which produces the nitrogen necessary for the growth of trees and that this organism is transferred to roots of the surrounding spruce trees. Once this infection has taken place, the presence of the mountain pine is no longer necessary and it is usually cut down. Clearly this is a biological relationship.

OOSPORES OF POTATO BLIGHT

THE potato blight fungus, *Phytophthora infestans*, has attracted more attention from botanists than almost any other fungus. The reasons for this are that under certain climatic conditions it causes sudden and widespread destruction of potato fields, and also that, though its life history has been carefully studied, the sexual or oospore stage has never been surely found. Berkeley, who was one of the earliest investigators to have a rational view of the cause of the epidemic of 1845, wrote at the time as follows:

> Few subjects have attracted more attention or have been more variously canvassed than the malady with which potatoes have been almost universally visited during the autumn of 1845. The press has teemed with notices the most contradictory, the attention of scientific men in every direction has been engaged by it, and three, at least, of the principal governments of Europe have issued commissions to examine into its etiology, and to discover, if possible, a remedy.

In 1875–76, at a time of considerable devastations of potato crops in Europe by the fungus, DeBary was employed by the Royal Agricultural Society of England to further investigate this fungus, while at about the same time Worthington G. Smith was engaged in similar work for the Royal Horticultural Society. As the result of their endeavors, considerable was learned concerning the life history of the fungus. Smith claimed to have found the oospores in the infested leaves and the old sets in great abundance, and was awarded a gold medal by the Royal Horticultural Society for his work. These bodies had been observed as early as 1845 by Rayer, Montagne and Berkeley. DeBary did not succeed in finding what he considered oospores of this fungus, and disputed Smith's claim with such good reasons that botanists generally believe that the oospores have never been discovered, though once or twice since investigators have claimed, without much conviction, to have found immature oogonia.

At the time of the controversy DeBary said:

> Ever since the oospores of a *Peronospora* were discovered, innumerable researches have been made for those of *Phytophthora*. I have myself looked for them for fifteen years, and on every opportunity have searched for them in the stalks, leaves, flowers, fruit and tubers of the potato. In July of the present year (1875), when the fungus appeared in this district in sad abundance, I obtained a very large amount of material for study, and at the same time secured the kindly assistance of two botanists experienced in researches of this kind, Dr. Rostafinski and Dr. Stahl. But again only negative results were arrived at. . . . That they will be regularly found somewhere or other is assured, for our knowledge of the habits of numerous allied fungi make this more than probable.

Smith deposited slides of his oospores with the British Museum. Concerning these Massee some time ago wrote me:

> I have very carefully examined W. G. Smith's type slide preparation, and am positively certain that the so-called oospores are nothing more than

the globose, thick walled chlamydospores belonging to a Fusarium

In a discussion following the Jones and Lutman paper at the American Association for the Advancement of Science meeting at Boston last year, Gussow said that he had seen these slides, and that the oospores much resembled the bodies that Jones and Lutman had obtained in their artificial cultures The writer has not seen these slides, though he tried to obtain examples of the oospores from Smith a few years ago Smith wrote at that time

> No doubt you know that the oospores became a kind of political subject—oospores of *P infestans* or not oospores of *P infestans*?—and I had no wish to go on Botanists and popular writers followed what they took to be the safer authority, just as Saccardo has done, this is right enough in a way

While we have not seen these slides, on every possible occasion during the eight years that we have been studying this fungus, we have looked for oospores in the leaves and tubers under the conditions described by Smith While we have never found spores that satisfied us that they were the potato blight oospores, we have found oospore-like bodies, both of animal and fungous origin, that might be mistaken for such, and possibly might be some of those bodies described by Smith We have seen Smith's drawings, and his photomicrographs published in the *Quarterly Journal of Microscopical Science*, Vol 15, in 1875, and the drawings of Montagne, published by Berkeley in the *Journal of the Horticultural Society*, Volume 1, in 1846, these latter being considered by Smith to represent the same thing he described as the oospores None of these impress us as being the same as the true oospores that we have obtained in cultures The only figures that at all show a resemblance are Figs 134 to 136 in Smith's book on "Diseases of Field and Garden Crops," published in 1884 We are inclined to believe that these botanists had a variety of things under consideration, and while it is quite doubtful if any of them were the oospores of potato blight, we do not wish to make a positive assertion without seeing the original preparations

In 1904 we first began to study the potato blight in artificial cultures So far as we know, we were the first to make such cultures in this country, or at least to publish notes on them,[1] but in looking up the literature at the time, it was found that two French botanists, Matruchot and Molliard, had secured cultures even earlier Their results, published in 1900 and 1903, were similar to those we had obtained, viz, the fungus was grown in certain media with fair success, but no oospores appeared, though we did very rarely find curious-shaped threads that might indicate futile attempts to form oogonia

At the Baltimore meeting of the American Association for the Advancement of Science, in December, 1908, Jones and Giddings gave a paper[2] in which they described these curiously shaped threads which had appeared with more or less frequency in stab cultures of a specially prepared potato-gelatin medium that they used Jones was inclined to believe that they were attempts at oogonial formation, though there were no indications of antheridia or oospores At the same meeting the writer[3] described a special medium, Lima bean juice agar, on which the potato blight grew with far greater vigor than on any medium yet tried, so that its continued cultivation was as easy as that of any parasitic fungus On this medium, however, no oospores appeared, and very rarely even the curious-shaped threads, though when *Phytophthora Phaseoli*, a near relative, was grown on it, oospores appeared in profusion

At the Boston meeting of the American Association for the Advancement of Science, Jones and Lutman gave a second paper[4] in which they further discussed these curious bodies that appeared in their cultures Though not stating positively that these bodies were of the nature of oogonia, they were inclined to consider them as resting spores While much

more successful in producing these bodies than previously, due in part to the use of the lima bean medium in a modified form, and while these bodies showed a still greater modification toward the oogonial type, they did not succeed in producing in their cultures any bodies of the nature of antheridia.

During the past year the writer, with the aid of his assistant, Mr E M Stoddard, has made still further tests with four strains of potato blight obtained from different sources, and with two of these (really one, as the other traces back to the same potatoes one season later) has obtained results far beyond anything yet reported These results were primarily due to the use of a new medium, which gave us for the first time very definite attempts at oospore formation, and with a certain modification of this medium *absolutely perfect oogonia, antheridia and even oospores have been obtained* We have not been successful, as yet, in producing the oogonia in cultures in anything like the abundance of those of *Phytophthora Phaseoli* and *Phytophthora cactorum* in the same medium, and very few of the oogonia produce even partially mature oospores, but of their nature there can be absolutely no doubt Whether or not we can perfect their formation in greater abundance remains to be seen, but recently, from an unusually good culture, a temporary slide preparation showed over a hundred of these oogonia, mostly without oospores or with immature ones; whereas last March the most we could find in similar slides were half a dozen or less

From the results of our recent investigation there is no doubt that the curious threads and bodies that Jones, and the writer to a much less extent, previously obtained, were attempts at the formation of oogonia We should judge, however, that Jones's cultural media, except for one particular, were not suited to perfect these bodies further, and that the excretory markings he obtained on the cell walls were largely abnormal. From my investigations it can be stated that the oogonia of the potato blight are thick-walled, with a more or less roughened or ornamented external coat, due to excretory thickening of the original wall, and are tinted more or less a chestnut brown The oospores are moderately thick-walled, smooth and colorless The oogonia are of a quite different type from those of both *P Phaseoli* and *P cactorum,* which are similar. The oogonia and oospores of these two are somewhat smaller than those of *P infestans,* but the chief difference is their smooth, hyaline, thin-walled oogonia

Not only has the writer obtained the oospores of *P infestans* in pure cultures, but he has also succeeded in raising what he considers crosses of this fungus with both *P Phaseoli* and *P cactorum* by inoculating a test-tube of the special medium with *P infestans* at the top and one or the other of these two species below With the growth of the two colonies together there appear in the vicinity of the *P infestans* colony not only the oospores of the other fungus but also oospores of the *P infestans* type These oospores of the *P infestans* type so far appear only rarely in the crosses with *P cactorum,* which, however, have only recently been made In the crosses with *P Phaseoli* the oospores of the *P infestans* type are more abundant than they have ever yet appeared under the most favorable conditions in pure cultures of *P infestans,* and many of them produced perfect oospores On the whole the oogonia and oospores appear to be somewhat larger and less deeply tinted than those from the pure cultures of *P infestans* Crosses between *P infestans* and *P. Phaseoli* made last March still continue to produce oospores of the *infestans* type, not usually as abundant as those of the *Phaseoli* type, however, though these cultures have been renewed six times since their original crossing These descendants are not from the oospores, since they never germinate in the cultures

From the data at hand it looks as though there were not two strains (male and female) of the potato blight, as we suggested some time ago, but that the potato fungus had largely lost its power to reproduce itself sexually. This loss may have come about by propagating it year after year asexually

through its hibernating mycelium in the potato tubers, just as the potato itself has largely lost its power to reproduce sexually through the formation of seeds This loss of sexual power is shown in different degrees by the different strains of the fungus in artificial cultures The fungus seems to lose first its power of producing antheridia and then of producing oogonia Under favorable conditions attempts to form oogonia first appear, and under still more favorable conditions the antheridia are produced, and with the formation of these the oospores also appear in more or less perfect form

A further discussion of this subject, with photomicrographs of the sexual stages as we have gradually developed them, will appear in the next report of the Connecticut Agricultural Experiment Station

A POSSIBLE LINE OF DESCENT OF THE GOBIOID FISHES

Indicating the doubt existing as to the relationship of the gobies are the several different positions assigned to them in the schemes of classification suggested from time to time by different authors Without attempting anything like an exhaustive survey of the disposition of the group by different authorities its treatment by a few of them may form an introduction to the suggestions of relationship in the following lines

Dr Gill, in his "Arrangement of the Families of Fishes,"[1] places the superfamilies Gobioidea and Cottoidea in adjoining groups But in his later arrangement[2] he has several families interposed between the Gobiidæ and Cottidæ, as the Batrachidæ, the Uranoscopidæ, the Trachinidæ, the Malacanthidæ and others

Dr Jordan, in his "Guide to the Study of Fishes,"[3] has placed the gobies near the cottoid fishes with the following remark "The great family of Gobiidæ, having no near relations among the spiny-rayed fishes, may be here treated as forming a distinct suborder"

Dr. Boulenger, in the Cambridge Natural History,[4] places the Gobiidæ between the Kurtidæ and Echeneididæ, and expresses the opinion that the gobies "are not very remote from the Perciformes, and may have evolved out of a type not very different from the Percidæ"

Mr Regan, in his classification of the teleostean fishes,[5] has placed the suborder Gobioidea between the Blennoidea and the Kurtoidei

Recently while examining the skeleton of *Dormitator maculatus*, a large goby from the warm waters of the American Pacific and Atlantic, I was impressed with the similarity of its shoulder girdle with that of the family Cottidæ and certain other cottoid or mail-cheeked fishes In light of the fact that there is otherwise very little in the anatomy of the gobies that might show their line of descent, I wondered that the line from some ancestor of the Cottidæ had not been long ago suggested, more especially as there seems to be little reason why such relationship should not exist.

The similarity of the shoulder girdles of these families has long been known As early as 1865 Dr Gagenbaur published a picture of the shoulder girdles of a gobioid and a cottoid fish side by side in the second part of his "Untersuchungen zur Vergleichenden Anatomie der Wirbelthiere."[6]

The condition of the shoulder girdle in the Cottidæ and Gobiidæ is as follows The coracoid elements and the actinosts are arranged in a continuous row on the posterior edge of the clavicle, the hypercoracoid above, next the actinosts, and ending below with the hypocoracoid—the actinosts attached directly with the clavicle, and separating the coracoid elements widely from each other. In the typical condition—the condition in the great majority of fishes—the coracoid elements are broadly attached to each other, and the actinosts are attached to their posterior edges remote from the clavicle

[1] "Smith Miss. Col.," 1872

[2] *Mem. Nat Acad. Sci*, Vol VI, pp. 127–138

[3] Henry Holt and Co, 1905.

[4] Macmillan and Co, 1904

[5] *Ann. Mag Nat Hist*, Ser 8, Vol III, 1909

[6] *Hemitripterus acadianus* and *Gobius guttatus*, Taf VII, figs 8 and 9

The fact that all of the mail-cheeked fishes do not have the coracoid elements separated by the actinosts is not an argument in disfavor of the relationship of the Gobiidæ to the Cottidæ, because the mail-cheeked fishes with the typical shoulder girdle (such as the Scorpænidæ) were, of course, the ancestors of the Cottidæ. From the Cottidæ came the Liparidæ and the Cyclopteryidæ, as Dr. Gill long ago pointed out.[7]

It does not seem improbable that the gobies may have come from some ancestor—probably scale-covered—of the Cottidæ in which the shoulder girdle had become differentiated. Further, it is not altogether improbable that this ancestor might also have been from somewhere along the line leading towards the Cyclopteryidæ and the Liparidæ, some form in which the ventrals had just become attached to each other, much as in most of the gobies of to-day. From this the sucking disk of the Liparidæ and Cyclopteryidæ could have developed. In considering this supposition, of course, we could only explain the gobies with separate ventrals by the separation being secondary. The gobies further resemble the last two families in having no myodome to the cranium.

It is conceded, certainly, that the family Gobiidæ is not very close to the Cottidæ, they having lost the suborbital stay to the preoperculum and undergone other changes, and no modification of the suborders containing these two families is suggested. The character of the shoulder girdle seems to be the most significant character in showing a possible line of descent of the gobies, and it is suggested in light of it that the group be placed in close relationship with the mail-cheeked fishes in works involving classification. With this question in mind the gobies should, of course, be studied in detail.

EDWIN CHAPIN STARKS

CARCHARIAS BORNEENSIS AND BARBUS ELONGATUS, AS PREOCCUPIED NAMES

IN the *Philippine Journal of Science*, Vol. V, No. 4, Section D, October, 1910, p. 263, Pl. 1, Mr. Alvin Seale describes, as new, "*Charcharias borneensis*." This is preoccupied by *Carcharias (Prionodon) borneensis* Bleeker, *Act. Soc. Sci. Ind.-Neerl.* (Borneo 12), V, 1858–59, p. 8.

In the same journal Mr. Seale also describes, as new, *Barbus elongatus*, on p. 265, illustrated on Pl. 2 as Fig. 1. This is preoccupied by *Barbus elongatus* Ruppell, Mus. Senckenb., II, 1837, p. 11, Pl. 2, Fig. 1.

SOCIETIES AND ACADEMIES

THE PHILOSOPHICAL SOCIETY OF WASHINGTON

THE 693d meeting was held on April 8, 1911, President Day in the chair. Three papers were read:

Mechanical Forces on an Electrical Conductor: DR. FRANK WENNER, of the Bureau of Standards.

Starting with the equation for the electromotive forces in an inductive circuit the speaker showed how it follows under certain conditions that a current through a conductor causes forces such as to require a tension in the conductor to maintain equilibrium, that is, the forces tend to increase the length of the conductor. It also follows that under other conditions the forces are such as to tend to decrease the length of the conductor. Under most conditions the force on an element of the conductor near the surface is such as to tend to crowd it toward the center.

It was also stated that it is possible that a current in a conductor causes forces other than those due to electro magnetic and electrostatic actions, the former only having been considered by the speaker. So far, however, no one has shown the presence of any such additional force.

The Completion of the Texas California Arc of Primary Triangulation: MR. WM. BOWIE, of the Coast and Geodetic Survey.

Three grades of triangulation are recognized: primary, secondary and tertiary; and the grade depends upon the accuracy of the angle and length measurements rather than upon the length of line between pairs of stations.

The primary work is extended in long arcs over

the area of a country to furnish control for the detailed operations The tertiary is used for the immediate control of detailed topographic, boundary and other surveys, while the secondary triangulation is mainly for the purpose of connecting the detached tertiary work with the primary schemes

Owing to the difference which must exist at every station between the geodetic position and the corresponding astronomic position, it is necessary to adopt a mean position called a geodetic datum upon which to reckon geographic positions over the entire country It is the principal object of the primary triangulation to carry standard positions by a connected net to the remotest portions of the area

An incidental purpose of triangulation, and especially of the primary, is to furnish means for determining the shape and size of the earth

In the two recent investigations of the figure of the earth by Mr John F Hayford, while he was inspector of geodetic work and chief of the computing division in the Coast and Geodetic Survey, he applied Pratt's hypothesis of isostasy and he stated that the application of this theory nearly doubled the accuracy of the results

Including about 2,000 miles by the Lake Survey, there are now approximately 11,000 miles of primary triangulation in the United States Recently about 400 miles have been added each year The latest addition is the Texas California triangulation, an arc of over 1,200 miles in length It extends from the 98th meridian triangulation in central Texas to the Pacific coast arc in the vicinity of San Diego It carries standard positions into an area badly in need of control and adds very valuable data for use in a future investigation of the figure of the earth

The probable errors of the observed directions are not available, as the office computations have not yet been made, but we may get a measure of the accuracy of the work by the size of the errors of closure of the triangles The average closing error is 0 9 second of arc, and the maximum error is very little more than 3 seconds This makes the accuracy equal to the average of the best half of the work previously done in the United States

The observations for horizontal measures were made entirely on heliotropes or on signal lamps No serious difficulty was encountered in observing over even the longest lines under average conditions The longest line was 127 miles in length Some of the heliotropes had reflectors 4 and 8 inches square but most of the reflectors were only 2½ inches in diameter The signal lamps burned acetylene gas They were the commercial automobile headlights, modified for use on a stand erected over the station

Some years ago it was believed that a great many observations were necessary to get an accuracy represented by an average closing error of one second and that the observations should be made on a number of different days In recent years only sixteen positions are used, making 32 pointings on each object All the horizontal observations at each of many stations have been made in a single day without materially affecting the accuracy In fact, the average accuracy of the work done under the present methods is greater than the average accuracy of the work previously done

It has been found that the sun effect on the towers, in causing twist, is very slight with the present type of tower, and that the effect, if any, is practically eliminated from the results by the system (always employed) of having a determination depend upon observations made while revolving the instrument clockwise and then in the reverse direction immediately afterwards

The instrument had one horizontal wire and two vertical ones which were 20″ apart It is not necessary for the image to be absolutely stationary for, with practise, one can place the cross wires close to the mean position of the image, even though the object may subtend an angle of more than 20″ and move 10″ to each side of the mean position Observations made under this condition seem to have about the average accuracy

Where the country is flat and the line close to the intervening land the wind tends to cause a distortion of the image It sometimes appears to flare to one side, the flaring being away from what seems to be the nucleus or center of the image In nearly every case where an asymmetrical image is observed the flaring seems to be with the wind Under such a condition it is difficult to make satisfactory observations If the flaring portion of the image is given equal weight with the nucleus a constant error is introduced, while if this flaring part is given no consideration a constant error of the opposite sign is made Such an image is a severe test of the skill of the observer

A remarkable case of lateral refraction was encountered on the twenty mile line joining stations Clayton and Kennard, in Texas This line passed very close to the west slope of a flat topped hill about two and a half miles from Clayton Observations made during several days at Clayton

on Kennard while the wind was blowing from the slope across the line were very unsatisfactory. When observations were made over the line with the wind blowing across it towards the slope of the hill, they were of the required degree of accuracy. The total range in the values for the several observing periods for this direction was about 8" of arc. During each observing period the range of the values for the sixteen pointings was small. It is believed that the air blown from the hill across the line was of a different temperature and was the cause of the lateral refraction.

The large errors in the observed directions of primary triangulation seem to be due to three principal causes. First, to the asymmetrical image of the light or heliotrope caused by wind when the line is low. Second, to lateral refraction, caused by a line passing close to a hillside or mountainside with the wind blowing from the slope across the line. Third, to the very unsteady lights when the instrument is low with the line passing close to the ground near the station. The first two causes produce constant errors, that is, each of the 32 measures is affected in the same direction. The last cause makes large accidental errors.

The Modern Potentiometer: Dr. W. P. WHITE, of the Geophysical Laboratory of the Carnegie Institution of Washington.

For many purposes it is desirable to avoid the slide wire. The construction of potentiometers of wide range in which only switches are used formerly presented difficulties, which have now been overcome. The modern all-switch potentiometer is characterized by three features: (1) the resistance is low, yet the switch contacts introduce no error; (2) the thermo electromotive forces at the switch contact and elsewhere must not cause variations in the reading; (3) the change of setting must not change the resistance of the galvanometer circuit, this in order that the partial deflection method may be employed. These three characteristics can not only be readily secured, but can be obtained in a number of different ways, so that three different types of instrument possessing them are now possible.

The main point of difference practically is concerned with the question whether certain switch contacts shall come in the battery circuit or in the galvanometer circuit. If they are in the battery circuit, much more care must be given to keep their resistance low, but this arrangement is best for reducing the thermoelectro forces. With the contacts in the galvanometer circuit, their resistance is unimportant, and the instrument therefore requires less care and attention; the thermoelectric forces can be practically avoided by proper switch construction, so that this arrangement seems preferable in a majority of cases.

(The abstracts of the second and last paper are by their authors.)

R. L. FARIS,
Secretary

THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 383d regular meeting was held April 1 in the lecture hall of the Cosmos Club with President David White in the chair and about a hundred persons present.

Under the heading brief notes and exhibition of specimens, F. V. Coville showed a pot of trailing arbutus (*Epigæa repens*) in full bloom. The plant had been grown in the greenhouse from the seed, and both foliage and blossoms were superior to those commonly found wild.

The following communications were presented:

A Day in the Galapagos Islands: WILLIAM EDWIN SAFFORD.[1]

The arboreous cereus of Charles Island has never been adequately described. It was said by Darwin to resemble *Cereus peruvianus* and compared by Engelmann with *Cereus multiangularis*. It is quite distinct from both these species. The well known *C. peruvianus* has only six to eight longitudinal ribs, while the Charles Island Cereus has sixteen to eighteen ribs. It is doubtful whether *C. multiangularis* is ever arboreous. Weber has described the Charles Island cereus under two names: *Cereus thouarsii*, which he characterizes as a columnar cereus with superimposed joints and pleasantly acidulous purplish-red, plum-like fruit containing soft white pulp and numerous small black seeds; *Cereus galapagensis*, as a plant resembling the arboreous cerei of South America, "with elevated angular stems exceeding the surrounding vegetation." Both of these descriptions apply well to the Charles Island cereus, illustrations of which, in flower, were presented by the author of the paper. The descriptions of both supposed species were published on the same page by Weber, and though *C. galapagensis* may be a preferable name, as it indicates the habitat of the species, *C. thouarsii* precedes it on the page, and must therefore be accepted.

Cereus thouarsii is remarkable for the long slender tube of its funnel-shaped perianth. The

[1] This paper is to be published in *The National Geographical Magazine*.

flowers are borne not near the apex, as in our giant cereus of Arizona, but along the sides of the branches and stems, often growing from areoles of the older or lower joints, solitary, yet often appearing from two or three adjacent areoles. The ripe fruits are very much like the *pitahayas* sold in Mexican markets. They are crowned by the withered perianth.

The joints, appearing in series and separated by abrupt constrictions, are sometimes five or six feet long, shaped like great ears of corn, or like thick-handled ten pins or indian clubs, or they are shorter and oval, resembling a series of melons piled one on top of the other, or they are sometimes spheroid, and the branches often form a divarication from one of the globose articulations. From the illustrations presented it is apparent that the arboreous cereus of Chatham Island is identical with that of Charles Island. It is to be regretted that figures of the flowers of Galapagos Cactaceæ are absolutely wanting thus far, though the islands have been repeatedly visited by scientific expeditions. The older specimens of *C. thouarsii* have stout cylindrical trunks covered with bark which splits into longitudinal strips.

The first description of an arboreous cereus growing in the Galapagos is that of the navigator Dampier, who visited the group in 1684. He described it as "a green prickly shrub ten to twelve feet high, as big as a man's leg and full of sharp prickles in thick rows from top to bottom, but without leaf or fruit." Colnett, in 1793, distinguished the cereus from the opuntia observed by him in the Galapagos, calling the first a "torch thistle" and the second a "prickly pear."

Captain David Porter was the first writer to call attention to the differences of the tortoises on the different islands of the Galapagos. His journal of the *Essex* was published twenty years before the visit of the *Beagle*. Figures were presented of two of the living tortoises from the Galapagos now in the National Zoological Park, *Testudo ephippium*, an example of what Captain Porter called the saddle backed form, and *Testudo vicina* Guenther, with a back of the form likened by Woods Rogers, the old sea rover, to the top of an old-fashioned hackney coach.

The figure of a fossil species, *Testudo osborniana* Hay, from the Miocene of northeastern Colorado, was also shown, and the question as to the possible connection of the Galapagos group with the main land during some part of the Tertiary age was discussed. The fact recorded by Captain Porter that tortoises thrown overboard from captured vessels remained floating and unharmed for several days, though unable to swim, was cited as bearing upon the point of the possible translation of the ancestors of the tortoises from the continent to the islands by ocean currents.

The paper ended with an account of the writer's visit to a hermit living in a cave in the interior of Charles Island, and of the animals which had become wild on the island, some of which had been caught when young and domesticated by the hermit. An account of the garden cultivated by the hermit was also given.

The Keys, Corals and Coral Reefs of Florida: T. WAYLAND VAUGHAN.

Dr. Vaughan gave a short lecture, illustrated by stereopticon views, on the subjects indicated by the title of his communication. He called attention to the extensive submarine plateau, of which the present land surface of Florida constitutes less than one half, and lies near the eastern margin. He briefly described the course of the 100-fathom curve and the steep declivity from it to the depth of 1,500 and 2,000 fathoms in the Gulf of Mexico, whereas between peninsular Florida and Cuba (except north of Havana) the depths are less than 500 fathoms. Between the northern end of the Bahama bank and the east coast of Florida the depth is somewhat less than 300 fathoms. The course of the 10 fathom curve was traced, and the relations it bears to the great barrier reef of Florida were indicated. The Hawk Channel, which lies between the line of reefs and the keys, the keys, and the bays and sounds between the keys and the mainland, were briefly described. A series of photographic slides were shown to illustrate the topography and geology of the mainland in the vicinity of Miami, and the surface features, including the vegetation, of the entire line of the Florida keys. The geologic formations of the region are of Pleistocene or recent age. The keys from Virginia Key at the north to Bahia Honda are elongated in a curve from northeast to southwest. Then follows the second group of keys including the Pine Keys, and extending to Boca Grande west of Key West are elongated in a direction at right angles to the axis of elongation of the more northerly keys, while the Marquesas and the Dry Tortugas are of atoll form. In composition the keys opposite the northern end of Bay Biscayne have a surface largely of siliceous sand. Those from Soldiers Key to the southern end of Big Pine Key are composed of elevated coral-reef rock—the Key Largo limestone. The keys from the Pine Keys

to Boca Grande are composed of an oolitic lime stone—the Key West oolite, which has been so recently elevated above sea level that its upper surface still shows sun cracks The Marquesas and the Tortugas keys are composed of the comminuted, calcareous tests of organisms

The geologic activity of mangroves in converting shallow submarine banks into land areas was described and illustrated by lantern slide photographs The fruit of these plants, which is a pod about six to nine inches long, falls into the water and catches on the soft ooze of shallow banks, where the young plants begin to grow, and after developing a tangle of roots below and a tangle of branches above the level of the water, catch and retain any drifting débris

The speaker then pointed out how fossil corals were utilized in ascertaining the depth and temperature conditions under which geologic formations containing the remains of these organisms were deposited The restriction of reef forming corals to shallow water and regions of high temperature, and the existence of a different fauna at depths below 100 fathoms and in regions of cooler temperature, were pointed out

Dr Vaughan then briefly outlined the study of the Florida corals, which he is conducting under the auspices of the Carnegie Institution of Washington, with reference to various factors that determine habitat and influence variation He showed that within the shallow water area of southern Florida there are several different faunal groups of corals that live under different conditions There are the reef corals proper, largely of massive type, that grow on the barrier reef Other corals, either of more fragile form of growth with a weaker basal attachment, or with ability to withstand deposits of silt over their upper surface, live on the flats protected from ocean breakers Other corals of a fragile habit of growth live in channels where they have a continuous supply of pure water and are protected from the breakers More fragile corals grow at the outer foot of a reef beneath the level of the pounding of the breakers than on the reef proper The forms that grow at the outer foot of the reef are to some extent similar to those that grow in the channels or along the margin of channels protected from the pounding of the breakers

The subject of the rate of growth of corals was briefly reviewed and the results of the investigations of Professor J Stanley Gardiner in the Maldive Islands were given Professor Gardiner there obtained a collection of corals none of which could have been more than three years of age, and on the basis of these observations estimated that the coral reef might increase one fathom in sixty years The observations of Gardiner are weak in that he did not definitely know the age of the individual specimens he obtained

Dr Vaughan has at present about 200 different coral colonies on which he is making annual measurements to determine the growth rate The colonies comprise the various conditions under which shallow water corals grow around the Tortugas, so that the investigations when completed will give the growth rate for each species investigated, and the variation in growth of each species in accordance with the conditions under which it lives in nature The results of the observations at present indicate that the rate of growth of corals is much more rapid than was previously anticipated, so that in a general way the opinions of Professor Gardiner are substantiated

The technique of obtaining specimens for planting was briefly described Besides those colonies that are naturally growing on the reefs or in other localities a number of specimens have been affixed by hydraulic cement to tiles, and the tiles have been planted on the heads of iron stakes driven in selected localities The tiles can be removed from the stakes, measured and photographed at desired intervals

Dr Vaughan also described the technique of rearing coral larvæ and the planting of the affixed young The larvæ are obtained from living corals brought into the laboratory and kept in jars of water The planulæ are then pipetted into a jar containing sea-water and a tile on its bottom After the planulæ have settled the tile is then planted Some of the tiles with attached larvæ were affixed to iron stakes in the sea and others were attached to the bottom of a floating livecar It has been ascertained that a *Favia* planula may attain a size of 9 mm in diameter within a period of seven months.

The duration of the free swimming larval stage of corals has been carefully studied in order to ascertain the possibilities of drift by ocean currents. The period varies from three or four days to three weeks—periods of ten to twelve days are common These observations have definitely shown that it is possible for coral larvæ to be drifted great distances by oceanic currents if the temperature conditions are favorable

THE BOLYAI PRIZE[1]

The problems treated by Hilbert are so varied and their importance is so evident that a long preamble seems unnecessary. It is preferable to enter immediately upon the detailed exposition of his principal memoirs. The reader in the presence of results so important will himself draw conclusions.

INVARIANTS

The first works of Hilbert relate to invariants. We know with what passion this part of mathematics was cultivated about the middle of last century and how it has since been neglected. It seemed in fact that Clebsch, Gordan, Cayley and Sylvester had used up all that it was possible to deduce from the old methods and that after them there remained only slight gleanings. But the progress of algebra and arithmetic, and in particular the theory of whole algebraic numbers, the extension soon made of it to integral polynomials, and Kronecker's theory of moduli, made possible the approach of the question from a side still unexplored.

This Hilbert did in attacking at first the celebrated theorem of Gordan, according to which all the invariants of a system of forms can be expressed in a rational and integral way as functions of a finite number of them.

We could not better measure the advance made than by comparing the volume Gordan had to devote to his demonstration with the few lines with which Hilbert has been satisfied. The method gained in gen-

[1] Report on the works of Hilbert by Poincaré. Translated by G. B. Halsted.

erality as much as in simplicity and one could make out a whole series of possible generalizations. A very simple lemma inspired by Kronecker's ideas had made this result possible.

Consider an indefinite series of forms F depending upon n variables, we can find among these a finite number of forms $F_1, \ldots, F_p$, such that any form F of the series can be equated to

$$F = A_1F_1 + \cdots + A_pF_p, \tag{1}$$

the A's being forms depending upon the same variables. This is a consequence of the fundamental notion of the modulus introduced by Kronecker. This means, in Kronecker's language, that the divisors common to many moduli, even were they infinite in number, are submultiples of one of them which is their greatest common divisor, and in geometric language (supposing four variables and regarding them as homogeneous coordinates of a point in space) that the aggregate of points common to an infinite number of algebraic surfaces is composed of a finite number of isolated points and a finite number of skew algebraic curves.

But this is not all, suppose the F's are the invariants of a system of forms and the A's functions of the coefficients of these forms.

We may always suppose that the A's are also invariants, otherwise we could perform an arbitrary linear transformation upon the forms. Then in the relation (1) thus transformed would appear the coefficients of this transformation. In applying to the relation (1) transformed a certain train of successive differentiations (the differentiations are performed with respect to the coefficients of the linear transformation) we reach a relation of the same form as (1) but where the A's are invariants. From this the proof of Gordan's theorem follows immediately.

But this is not all, among these fundamental invariants there is a certain number of relations called syzygies. All the syzygies can be deduced from a finite number of them by addition and multiplication. Among these fundamental syzygies of the first order there are syzygies of the second order, which can also be obtained from a finite number of them by addition and multiplication, and so on.

Hilbert gets this result from a general theorem of algebra. Consider a system of linear equations of the form

$$\Sigma F_{ik} X_k = 0,$$

where the F's are given forms and the X's unknown forms homogeneous in regard to certain variables, the study of the solutions of this system and of the relations which connect them leads to the consideration of a series of derived systems continued until we reach a derived system which no longer admits of any solution. Thus it was that Hilbert was led to determine and to study the number $\chi(R)$ of distinct conditions which a form of degree R should satisfy to be congruent to zero with regard to a given modulus.

But to complete the theory it was not enough to establish the existence of a system of fundamental invariants, it was necessary to give the means of actually forming this, and this problem was made by our author to depend upon a question which connects it with the theory of whole algebraic numbers extended to integral polynomials.

The problem is thus broken up into three others.

1. To find invariants J_m as functions of which all the others can be expressed in *algebraic and integral* form, that is to say, such that any invariant J satisfies an algebraic equation

$$J^k + G_1J^{k-1} + G_2J^{k-2} + \cdots + G_{k-1}J + G_k = 0,$$

the G's being polynomials integral with regard to J_m.

2. To find invariants as functions of which all the others can be expressed rationally.

3. To find invariants as functions of which all the others can be expressed in rational and integral form.

Of these three problems the first is the most difficult. If it be supposed solved, the aggregate of invariants presents itself as an *algebraic corpus*, and the first step to make is to determine the degree of this corpus; this it is at which Hilbert arrives at least for binary forms by evaluating in two different ways the number $\phi(\sigma)$ of invariants linearly independent of degree σ, or rather the asymptotic value of this numeric function $\phi(\sigma)$ for σ very great.

The first problem once solved, the solution of the other two goes back to a classic question of the arithmetic of polynomials and of the theory of algebraic corpora. The question is then to find the fundamental invariants by whose aid all the others can be expressed in algebraic and integral form.

With this purpose Hilbert remarks that these are those which can not be annulled without annulling all the others. So we see that the search for these fundamental invariants will be singularly facilitated by the study of *null forms*, that is to say, of those whose numeric coefficients are chosen in such a way that the numeric values of all the invariants may be null.

In the case of binary forms, the null forms are those which are divisible by a sufficiently high power of a linear factor, but in the other cases the problem is more delicate. Our author first establishes a certain number of theorems.

Consider a form with numeric coefficients and its transform by any linear substitution; the coefficients of this transform will be integral polynomials with regard to the coefficients of the substitution. If the determinant of the substitution is an *algebraic and integral* function of these integral polynomials, the proposed form is not a null form. In the contrary case, it is a null form.

Consider, on the other hand, the transforms of a form by a linear substitution depending upon an arbitrary parameter t and in such a way that the coefficients of this substitution are series developable in positive or negative integral powers but increasing with this parameter. If it be a question of a null form, we can choose a substitution of this kind of such a sort that its determinant becomes infinite for $t = 0$, while the coefficients of the form transformed remain finite. Hilbert shows that this condition is necessary in order that the proposed form may be null, and it is evident, moreover, that it is sufficient. To each null form corresponds therefore one and perhaps several linear substitutions having the enunciated property. This settled our author proves that, starting from any null form, we can by a linear transformation, transform it into a *canonic* null form. A form is called canonic when the linear substitution which corresponds to it and which possesses in relation to it the property we have just stated is of the simple form

$$\begin{vmatrix} t^{\lambda_1} & 0 & 0 \\ 0 & t^{\lambda_2} & 0 \\ 0 & 0 & t^{\lambda_3} \end{vmatrix}$$

The investigation of null forms is thus made to depend on that of canonic null forms which is much more simple. We find that the canonic null forms are those in which certain terms are lacking, and the determination of the terms which should be lacking can easily be made, thanks to a simple geometric scheme.

We see under what a new and elegant aspect present themselves to-day, thanks to Hilbert, problems so many geometers had for fifty years attempted

THE NUMBER e

Hermite was the first to prove that the number e is transcendant, and shortly afterward Lindemann extended this result to the number π

This was a victory important for science, but Hermite's methods were still susceptible of betterment, however ingenious and however original they were, one felt they did not lead to the goal by the shortest way This shortest way Hilbert has found, and it seems that henceforth no one can hope to give new simplification to the proof

This was the second time that Hilbert had given, of a theorem known but only established by means most arduous, a proof of astonishing simplicity This faculty of simplifying what had seemed at first complex thus presents itself as one of the characteristics of his genius

ARITHMETIC

The arithmetical works of Hilbert pertain principally to algebraic corpora The aggregate of numbers which can be expressed rationally as functions of one or several algebraic numbers constitutes a domain of rationality, and the aggregate of the numbers of this domain which are algebraic integers constitutes a corpus If we consider then all the algebraic numbers of a corpus which can be put under the form

$$a_1x_1 + a_2x_2 + \cdots + a_px_p$$

where the a's are *given* numbers of the corpus, and the x's indeterminate numbers of the same corpus, the aggregate of these numbers is what is called an *ideal*. That which gives interest to this consideration is that the ideals obey in what concerns their divisibility the ordinary laws of arithmetic and that in particular every ideal is decomposable in one way and only one into ideal primes This is the *fundamental theorem of Dedekind*

On the other hand, we may consider numbers which satisfy an algebraic equation of which the coefficients belong to a domain D of rationality These numbers and those rationally expressible by means of them define a new domain of rationality D' more extended than D, and an algebraic corpus K' more extended than the corpus K which corresponds to D. We then may relate the corpus K', not to the ordinary rational numbers and to the corpus of the integers of ordinary arithmetic, but to the domain D and to the algebraic corpus K We then may speak of the *relative* degree of K' with reference to K, of the *relative norm* of an algebraic number of K' with reference to K, etc There will be corpora relatively quadratic obtained by the adjunction to the domain D' of a radical $\sqrt{\mu}$, μ being a number of the domain D, and corpora relatively abelian, obtained by the adjunction to D of the roots of an abelian equation This is a sort of generalization of the ideas of Dedekind, that Hilbert is doubtless not the first to have seen, but from which he has drawn an unexpected advantage.

We should also speak of galois corpora, whose generating equation is a galois equation. Any corpus is contained in a galois corpus, in the same way the corpus K of which we have just spoken is contained in the corpus K'; and this galois corpus is easily obtained by adjoining to the domain of rationality, not only one of the roots of the generating algebraic equation of K, but *all* its roots

Questions relative to any corpus are

thus made to depend upon the analogous problems for the galois corpora

After having shown how we may, by the discussion of a congruence, form all the ideals of given norm, Hilbert has sought a new proof of the fundamental theorem of Dedekind, he established it first for the galois corpora and then easily extended it to any corpus.

Thus Hilbert was led to study the general theory of galois corpora, and he introduced a host of new notions, defining a series of subcorpora, corresponding to different subgroups of the galois group of the generating equation, these subgroups are defined by certain relations they have with any ideal prime of the corpus, and the study of these subgroups opens for us glimpses new and interesting of the structure of the corpus.

Our author gave in 1896 a new proof of Kronecker's theorem according to which the roots of abelian equations can be expressed by the roots of unity This demonstration purely arithmetical puts in evidence the way of constructing all the abelian corpora of a given group and discriminant

But the works of Hilbert have had as their principal object the study of corpora relatively quadratic and relatively abelian

One of the essential points of the theory of numbers is Gauss's law of reciprocity in the subject of quadratic residues, we know with what predilection the great geometer returned to this question and how he multiplied demonstrations.

This law of reciprocity is capable of interesting generalizations when we pass from the domain of ordinary rational numbers to a domain of any rationality Hilbert has succeeded in realizing this generalization in the case where the corpus is imaginary and has an odd number of classes. He has introduced a symbol analogous to that of Legendre, and the law of reciprocity reached by him presents itself in a simple form, the product of a certain number of such symbols must equal 1

This generalization presents all the more interest since our author has succeeded in showing that there are genera corresponding to half of all the imaginable systems of characters, a result which should be likened to that of Gauss and which makes possible the extension to a domain of any rationality of this notion of the genus of quadratic forms which is the subject of one of the most attractive chapters of the "Disquisitiones Arithmeticæ"

To go farther, Hilbert is obliged to introduce a new notion and modify the definition of class

Two ideals belong to the same class in the old or broad sense if their ratio is any existing algebraic number, they belong to the same class in the new or narrow sense if their ratio is an existing algebraic number *which is positive as well as all its conjugates* The numbers of classes, whether understood in the broad sense or in the narrow sense, are evidently in intimate relation and our author explains what the nature of this relation is But this new definition allows Hilbert to express in simpler language the theorems he had in view These theorems stated in their most general form are, as Hilbert says, remarkably simple and of crystalline beauty, their complete proof appeared to our author as the final aim of his studies on algebraic corpora It is in this general form we shall state them

If k is any corpus, there is a group Kk which may be called its *class corpus*. Its relative degree is equal to the number of classes in the narrow sense. It is non-ramified, that is to say, no ideal prime of k is divisible by the square of an ideal prime of Kk, and it contains all the non-ramified

corpora relatively abelian with regard to k

Its relative group is isomorphic to the abelian group which defines the composition of the classes of ideals of k

The ideal primes of k, although prime in relation to k, are not in general prime in relation to Kk, they may, therefore, be broken into factors ideal primes with regard to Kk, the number of these factors and the power to which they are raised, in a word the mode of partition, depending solely upon the class to which the ideal considered belongs in the corpus k

Call "*ambige*" a number of Kk which is positive as well as all its conjugates, and which differs from these conjugates only by a factor which is a complex unity

Each ambige of Kk corresponds to an ideal of k and reciprocally This property is characteristic of the corpus Kk among all the corpora relatively abelian with regard to k

We see the bearing of these theorems and the light thrown on the notion of class, since the mutual relations of classes of ideals are reproduced as in a faithful picture by those of the algebraic integers of a corpus

In reality Hilbert has completely proved these theorems only in particular cases, but these particular cases are very numerous, exceedingly varied and broadly extended He is, besides, he says, convinced that his methods are applicable to the general case While sharing his conviction, we must make reservation, so long as this hope, legitimate as it may be, has not been actually realized

We have spoken above of the law of reciprocity relative to quadratic residues, we must add that Hilbert has given an analogous law for his residues of any power, at least for certain particular corpora

Summarizing, the introduction of ideals by Kummer and Dedekind was an important advance, it generalized and at the same time cleared up the classic results of Gauss on quadratic forms and their composition The works of Hilbert we have just analyzed constitute a new step in advance, not less important than the first

THEOREM OF WARING

Let us speak now of another entirely different arithmetical work It pertains to proving Waring's theorem according to which every integer can be broken into a sum of N nth powers, N depending only upon n, just as, for example, it can always be broken into a sum of four squares Needless to recall that this theorem up to the present had simply been stated

What above all deserves to fix the attention in Hilbert's proof is that it rests on a new way of introducing continuous variables into the theory of numbers

We start from an identity where a 25uple integral is equated to the mth power of the sum of five squares Breaking up the domain of integration into smaller domains so as to have a series of approximate values of the integral, as if it were a question of evaluating it by mechanical quadratures, and by the methods of passing to the limit familiar to our author, we reach another identity

$$(x_1^2 + \quad + x_5^2)^m = \Sigma r_h Y_h^{2m},$$

where the r_h's are rational positive numbers and the Y's linear functions of the x's with integral coefficients The coefficients r and those of the Y's, as also the number of these linear functions, depend only upon m.

Up to this point we have not gone out of algebra, if not in showing that the coefficients r and those of Y are rational. To get further our author establishes a series of lemmas whose statement is too complicated to be here reproduced and which

lead finally to the complete proof of the theorem We can not doubt that these considerations, which allow also the obtaining of arithmetical relations in making them come from identities where definite integrals figure, can some day, when we shall have grasped their meaning, be applied to problems much more extended than that of Waring

GEOMETRY

I come to Hilbert's works so very original on the foundations of geometry

There are in the history of this geometric philosophy three principal epochs, the first is that where thinkers at whose head we should cite Bolyai founded the non-euclidean geometry, the second is that in which Helmholtz and Lie showed the rôle in geometry of the notion of motion and of group; the third was inaugurated by Hilbert

The German author takes the logical point of view What are the axioms enunciated and those unconsciously assumed, what is their real logical content and what may be deduced from them by the simple application of the rules of logic and without new appeal to intuition? Finally, are they independent, or can we on the contrary, deduce them from one another? These are the questions to face

Hilbert commences, therefore, by establishing the complete list of assumptions, striving not to forget a single one That is not as easy as one might think, and Euclid himself uses some he does not state Geometric intuition is so familiar to us that we use intuitive verities, so to speak, without our perceiving them, hence to attain the aim Hilbert proposed to himself, the necessity of not according to intuition the least place

The savant professor divides the assumptions into five groups:

I Assumptions of Association (I shall translate by *projective assumptions* in place of seeking a literal translation, as, for example, *assumptions of connection*, which would not be satisfactory)

II Betweenness assumptions (assumptions of order)

III Congruence assumptions or metric assumptions

IV Euclid's postulate

V The Archimedes assumption

Among the projective assumptions we distinguished those of the plane and those of space, the first come from the well-known proposition *through two points passes one straight, and only one*

Going on to the second group, the order assumptions, here is the statement of the first two.

"If three points are on the same straight, they have a certain relation which we express by saying that one of the points, and only one, is between the other two If C is between A and B, if D is between A and C, D will also be between A and B, etc "

Here still we note that intuition is not brought in, we seek not to fathom the meaning of the word *between*, every relation satisfying the assumptions may be designated by this same word

The third group comprises the metric assumptions where we distinguish three subgroups, relative respectively to sects, to angles and to triangles

An important point here was not stressed (in the first German edition, though it appears in the French translation) To complete the list of assumptions it needs to be said that the sect AB is congruent to the inverse sect BA This assumption implies the symmetry of space and the equality of the angles at the base in an isosceles triangle Hilbert does not here treat this question, but he has

made it the subject of a memoir to which we shall return later

The fourth group contains only Euclid's postulate

The fifth group comprises two assumptions, the first and most important is that of Archimedes

Let there be any two points A and B on a straight d, let a be any sect, construction d, starting from the point A, and in the sense AB, a series of sects all equal to one another and equal to a

AA_1, A_1A_2, $A_{n-1}A_n$; we can always take n so great that the point B is on one of these sects

This is to say that, if we take any two sects l and L, we can always find a whole number n so great that by adding the sect l to itself n times, we obtain a total sect greater than L

The second is the assumption of completeness of which I shall explain the meaning further on

INDEPENDENCE OF THE ASSUMPTIONS

The list of assumptions once drawn up, it is necessary to see if it is free from contradictions We well know that it is, since geometry exists, and Hilbert first replied yes by constructing a geometry But strange to say, this geometry is not exactly ours, his space is not ours, or at least is only a part of it. In Hilbert's space are not all the points which are in ours, but only those that, starting from two given points, we can construct with ruler and compasses In this space, for example, there is no angle of 10°.

In his second edition Hilbert tried to fill out his list so as to obtain our geometry and no other, and so he introduced the assumption of completeness which he states as follows·

To the system of points, straights and planes it is impossible to adjoin another system of objects such that the complete system satisfies all the other assumptions.

It is evident then that this space of which I spoke, which does not contain all the points of our space, does not satisfy this new axiom, because we can adjoin to it those points of our space which it does not contain, without its ceasing to satisfy all the assumptions.

There is, therefore, an infinity of geometries which satisfy all the assumptions except the assumption of completeness, but only one, ours, which satisfies also this latter assumption

We then must ask if the assumptions are independent, that is to say, if we could sacrifice one of the five groups, retaining the other four, and nevertheless obtain a coherent geometry Thus it is, suppressing group IV (Euclid's postulate), we obtain Bolyai's non-euclidean geometry

We can equally suppress group III Hilbert has succeeded in retaining groups I, II, IV and V, as also the two subgroups of the metric assumptions of sects and angles, while rejecting the metric assumption of triangles, that is to say, the proposition III., 6

Non-archimedean Geometry.—But Hilbert's most original conception is that of non-archimedean geometry, where all the assumptions remain true save that of Archimedes For this it is needful first to make a ***system of non-archimedean numbers***, that is to say, a system of elements between which we can conceive relations of equality and inequality, and to which we can apply operations corresponding to arithmetical addition and multiplication, and this in a way to satisfy the following conditions:

1. The arithmetical rules of addition and of multiplication (commutativity, associativity, distributivity, etc., *arithmetical*

assumptions of combination) remain without change

2 The rules of the calculus and transformation of inequalities (arithmetical assumptions of ordering) likewise remain

3 The Archimedes assumption is not true

We may attain this result by choosing for elements series of the following form

$$A_0 t^m + A_1 t^{m-1} + A_2 t^{m-2} + \quad ,$$

where m is an integer positive or negative and where the coefficients A are real, and convening to apply to these series the ordinary rules of addition and of multiplication It is necessary then to define the conditions of inequality of these series so as to *arrange* our elements in a determined order We shall attain this by the following convention we will attribute to our series the sign of A_0 and we will say that a series is smaller than another when, if taken away from this, it gives a positive difference

It is clear that with this convention the rules of the calculus of inequalities hold good, but the Archimedes assumption is no longer true

Our common numbers come in as particular cases among these *non-archimedean numbers* The new numbers intercalate themselves, so to speak, in the series of our common numbers, in such a way that there is for example an infinity of new numbers less than a given common number A and greater than all the common numbers less than A

That settled, imagine a tri-dimensional space wherein the coordinates of a point are measured not by common numbers, but by non-archimedean numbers, but where the usual equations of the straight and of the plane hold good, as also the analytic expressions for angles and sects It is clear that in this space all the assumptions remain true, save that of Archimedes

On any straight between our common points would intercalate themselves new points Likewise there will be on this straight an infinity of new points to the right of all the common points In a word, our common space is only a part of non-archimedean space

We see what is the bearing of this invention and wherein it constitutes in the progress of our ideas a step almost as bold as that which Bolyai made us take, the geometry non-euclidean respected, so to speak, our qualitative conception of the geometric continuum while it overturned our ideas on the measure of this continuum The non-archimedean geometry destroys this conception, it dissects the continuum to introduce into it new elements

In this conception so audacious Hilbert had had a precursor In his foundations of geometry Veronese had had an analogous idea Chapter VI of his introduction is the development of a veritable non-archimedean arithmetic and geometry where the transfinite numbers of Cantor play a preponderant rôle Nevertheless, by the elegance and simplicity of his exposition, by the depth of his philosophic views, by the advantage he has derived from the fundamental idea, Hilbert has made the new geometry his own

Non-arguesian Geometry—The fundamental theorem of projective geometry is the theorem of Desargues

Two triangles are called *homologs* when, the straights joining each to each, the corresponding vertices are copunctal. Desargues proved that the intersection points of the corresponding sides of two homologous triangles are costraight, the dual is equally true

The theorem of Desargues can be established in two ways:

1 By using the projective assumptions of the plane and the metric assumptions of the plane

2 By using the projective assumptions of the plane and those of space

Therefore, the theorem could be discovered by a two-dimensional animal, to whom a third dimension would seem as inconceivable as to us a fourth, who consequently would not know the projective assumptions of space, but who would have seen displaced in the plane he inhabited rigid figures analogous to our solid bodies, and who consequently would know the metric assumptions Equally well the theorem could be discovered by a tri-dimensional animal who should know the projective assumptions of space, but who, having never seen solid bodies displaced, would not know the metric assumptions

But would it be possible to establish the theorem of Desargues without using either the projective assumptions of space or the metric assumptions, but only the projective assumptions of the plane? It was thought not, but we were not sure Hilbert has settled the question by constructing a *non-arguesian geometry,* which is of course a plane geometry

Non-pascalean Geometry—Hilbert does not stop there, he introduces still a new conception To understand it, we must return a moment to the domain of arithmetic We have above seen the notion of number enlarged by the introduction of *non-archimedean numbers* We need a classification of these new numbers, and to get it we first classify the assumptions of arithmetic into four groups

1 The laws of associativity and of commutativity of addition, the associative law for multiplication, the two laws of distributivity of multiplication, or, to summarize, all the rules of addition and of multiplication, save the law of the commutativity of multiplication

2 The assumptions of order, that is to say, the rules of the calculus of inequalities.

3 The law of commutativity of multiplication according to which we can invert the order of the factors without changing the product

4 The Archimedes assumption

The numbers which admit the first two groups are called *arguesian;* they may be *pascalean* or *non-pascalean,* according as they satisfy or do not satisfy the assumption of the third group, they will be *archimedean* or *non-archimedean,* according as they satisfy or do not the assumption of the fourth group We soon shall see the reason for these names

The ordinary numbers are at once arguesian, pascalean and archimedean We can prove the law of commutativity from the assumptions of the first two groups and the Archimedes assumption, so there are no numbers arguesian, archimedean and not pascalean

On the other hand, it is easy to make a system of numbers arguesian, non-pascalean and non-archimedean The elements of this system will be series of the form

$$S = T_0 s^n + T_1 s^{n-1} + \quad ,$$

where s is a symbol analogous to t, n an integer positive or negative, and T_0, T_1, numbers of the system T If therefore we replace the coefficients T_0, T_1, by the corresponding series in t, we shall have a series depending at the same time upon t and upon s We add these series S according to the ordinary rules, and likewise for the multiplication of these series, we shall admit the rules of distributivity and of associativity, but we shall hold that the law of commutativity is not true and that, on the contrary, $st = -ts$

It remains to *arrange* these series in an order so determined as to satisfy the assumptions of order. For that, we give to the series S the sign of the first coefficient

T_0; we shall say that a series is less than another, when if taken away from this, it gives a positive difference This, therefore, is always the same rule t is looked upon as very great with regard to any ordinary real number, and s is looked upon as very great with regard to any number of the system T

The law of commutativity not being true, these now are non-pascalean numbers

Before going farther I recall that Hamilton long ago introduced a system of complex numbers where the multiplication is not commutative, these are the *quaternions*, which the English so often use in mathematical physics But, for quaternions the assumptions of order are not true, what therefore is original in Hilbert's conception is that his new numbers satisfy the assumptions of order without satisfying the rule of commutativity

To return to geometry Admit the assumptions of [the first] three groups, that is to say, the projective assumptions of the plane and of space, the assumptions of order, and Euclid's postulate, the theorem of Desargues will follow from them since it is a consequence of the projective assumptions of space

We wish to establish our geometry *without using metric assumptions*, the word *length* therefore has now for us no meaning, we have no right to use the compasses, on the other hand, we may use the ruler, since we admit that we may pass a straight through two points, in virtue of one of the projective assumptions, equally we know how through a point to draw a parallel to a given straight, since we admit Euclid's postulate. Let us see what we can do with these resources

We can define the homothety (perspective similarity) of two figures, and through it proportion. We can also define equality in a certain measure

The two opposite sides of a parallelogram shall be equal *by definition*, thus we know how to recognize whether two sects are equal to one another, *provided they be parallel*

Thanks to these conventions, we now are prepared to compare the lengths of two sects, but *with the proviso that these sects be parallel*

The comparison as to length of two sects differing in direction has no meaning, and there would be needed, so to speak, a different unit of length for each direction It is unnecessary to add that the word *angle* has no meaning.

Sects will thus be expressed by numbers, but necessarily these will not be ordinary numbers All we can say is that if the theorem of Desargues is true, as we suppose, these numbers will belong to an *arguesian system*

Inversely, having given any system S of arguesian numbers, we can make a geometry such that the lengths of the sects of a straight may be exactly expressed by these numbers

The equation of the plane will be a linear equation as in the ordinary analytic geometry, but since in the system S multiplication will not be commutative, in general it is needful to make a distinction and to say that in each of the terms of this linear equation the coordinate will play the rôle of multiplicand, and the constant coefficient the rôle of multiplier

Thus to each system of arguesian numbers will correspond a new geometry satisfying the projective assumptions and those of order, the theorem of Desargues and Euclid's postulate What now is the geometric meaning of the arithmetical assumption of the third group, that is to say, of the rule of commutativity of multiplication?

The geometric translation of this rule is

Pascal's theorem; I mean the theorem about the hexagon inscribed in a conic, supposing that this conic reduces to two straights So Pascal's theorem will be true or false according as the system S is pascalean or non-pascalean, and since there are non-pascalean systems, *there likewise are non-pascalean geometrics* The theorem of Pascal can be deduced from the metric axioms, it therefore will be true if we suppose figures may be transformed not only by homothety and translation, as we have done, but also by rotation Pascal's theorem can likewise be deduced from the Archimedes axiom, since we have seen that every system of numbers arguesian and archimedean is at the same time pascalean, *every non-pascalean geometry is therefore at the same time non-archimedean*

The Sect-carrier—We cite still another conception of Hilbert's He studies the constructions we can make, not with ruler and compasses, but with ruler and a special instrument which he calls the *sect-carrier,* and which enables us to set off on a straight a sect equal to another sect taken on another straight The *sect-carrier* is not the equivalent of the compasses, this latter instrument enables us to construct the intersection of two circles, or of a circle and any straight, the *sect-carrier* will only give us the intersection of a circle and a straight *passing through the center of this circle.* Hilbert seeks therefore what are the constructions which are possible with these two instruments, and he reaches a very remarkable conclusion.

The constructions which can be achieved with ruler and compasses can likewise be made with the ruler and the *sect-carrier, provided these constructions are such that their result is always real.*

It is evident in fact that this condition is necessary, because a circle is always cut *in two real points* by a straight drawn through its center But it was hard to foresee that this condition would likewise be sufficient.

But this is not all, in all these constructions, as Kürschák first noticed, it is possible to replace the *sect-carrier* by the *unit-sect carrier,* an instrument which enables us to set off on any straight from any point of it, no longer any sect, but a sect equal to unity

An analogous question is treated in another article of Hilbert's *On the equality of the angles at the base of an isosceles triangle*

In the ordinary plane geometry, the plane is symmetric, which expresses itself in the equality of the angles at the base of the isosceles triangle

We should make this *symmetry of the plane* appear in the list of metric assumptions In all the geometrics more or less strange of which we have spoken hitherto, in those at least where we admit the metric assumptions, in the non-archimedean metric geometry, in the new geometries of Dehn, in those which are the subject of the memoir "On a New Foundation, etc," this symmetry of the plane is always supposed Is it a consequence of the other metric assumptions? Yes, as Hilbert shows, if we admit the Archimedes assumption No, in the contrary case There are non-archimedean geometries where all the metric assumptions are true with the exception of this of the symmetry of the plane

In this geometry it is not true that the angles at the base of an isosceles triangle are equal, it is not true that in a triangle one side is less than the sum of the other two, the theorem of Pythagoras about the square on the hypothenuse is not true. That is why this geometry is called *non-pythagorean.*

I come to an important memoir of Hil-

bert's which is entitled "Foundations of Geometry," which bears then the same title as his "Festschrift," but where he takes, however, a wholly different point of view In his "Festschrift," in fact, as we have seen by the preceding analysis, the relations of the notion of space and the notion of group resulting from the works of Lie are laid aside or relegated to an inferior place The general properties of groups do not appear in the list of fundamental assumptions Not so in the memoir of which we are to speak

As regards the ideas of Lie, the progress made is considerable Lie supposed his groups defined by analytic equations. Hilbert's hypotheses are far more general Without doubt this is still not entirely satisfactory, since though the *form* of the group is supposed any whatever, its *matter*, that is to say, the plane which undergoes the transformations, is still subjected to being a *number-manifold* in Lie's sense Nevertheless, this is a step in advance, and besides Hilbert analyzes better than any one before him the idea of *number-manifold* and gives outlines which may become the germ of an assumptional theory of analysis situs

It is impossible not to be struck by the contrast between the point of view here taken by Hilbert and that adopted in his "Festschrift" In this "Festschrift" the continuity assumptions took lowest rank and the great thing was to know what geometry became when they were put aside Here, on the contrary, continuity is the point of departure and Hilbert is above all anxious to see what we get from continuity alone, joined to the notion of group

It remains for us to speak of a memoir entitled "Surfaces of Constant Curvature."

We know that Beltrami has shown that there are in ordinary space surfaces which image the non-euclidean plane, these are the surfaces of constant negative curvature, we know what an impulse this discovery gave to the non-euclidean geometry But is it possible to represent the non-euclidean plane entire on a Beltrami surface without singular point? Hilbert has proved that it is not

As to the surfaces of constant positive curvature, to which Riemann's geometry corresponds, Hilbert proves that besides the sphere there is no other closed surface of this sort

(*To be concluded*)

SCIENTIFIC NOTES AND NEWS

DR DAVID STARR JORDAN has tendered to President Taft his resignation as international commissioner of fisheries, this position having been created three years ago under the treaty of April 11, 1908, with Great Britain Under the terms of the appointment, the work of the commissioner ceases on the completion of the series of fishery regulations of the boundary waters, and the technical investigations necessary for their completion This work being finished, the administration of the treaty passes to the Bureau of Fisheries

DR. WILLY KUKENTHAL, professor of zoology at Breslau, has been appointed exchange professor at Harvard University during the academic year of 1911–12

DR EDWARD MINER GALLAUDET has retired from the presidency of Gallaudet College, which he has held for fifty-four years

DR. OSCAR RIDDLE, of the University of Chicago, has returned from a year of study and travel in Europe He spent the past six months at the Zoological Station at Naples, whence he now returns to Chicago to take charge of the preparation for publication of the manuscripts left by the late Professor C. O Whitman He will also continue certain features of Professor Whitman's investigations

PROFESSOR GEORGE E SEVER has been elected president of the Columbia Chapter of

Sigma Xi as successor to Professor William H. Burr.

DR. F. E. CLEMENTS, professor of botany in the University of Minnesota, has been elected president of the Chapter of Sigma Xi in that university.

MR. W. C. COX, of the U. S. Forest Service, has been appointed to the newly created post of state forester of Minnesota.

AT a meeting of the Royal Dublin Society held on April 25, the Boyle medal of the society was presented to Professor John Joly, F.R.S., whose researches deal with physics, geology, mineralogy, botany and biological theory.

PROFESSOR A. C. SEWARD, F.R.S., has been elected president of a newly established Cambridge University Eugenics Society.

THE council of the Institution of Civil Engineers has made the following awards for papers read and discussed during the session 1910–11: Telford gold medals to Mr. W. J. Wilgus (New York) and Mr. J. Walker Smith (Edinburgh); a George Stephenson gold medal to Mr. Philip Dawson (London), Telford premiums to Messrs. G. W. Humphreys (London), H. K. G. Bamber (Greenhithe), A. E. Carey (London), William Dawson (Crewe) and C. S. R. Palmer (London), and the Trevithick premium to Mr. A. T. Blackall (Reading).

JOSIAH ROYCE, professor of the history of philosophy at Harvard, will be the university delegate at the celebration of the five hundredth anniversary of the University of St. Andrews.

THE American Philosophical Society has made the following appointments of delegates to represent it: At the jubilee of Professor Giovanni Copellini, to be held at Bologna on June 12 next, Professor Dott. Guglielmo Mengairni, of Rome. At the tenth International Congress of Geography to be held at Rome from October 15 to 22, 1911, Mr. Henry G. Bryant. At the thirtieth Congres National des Sociétés Françaises de Géographie to be held at Roubaix, France, from July 29 to August 5, 1911, Mr. Julius F. Sachse.

MR. C. W. BEEBE, curator of ornithology of the N. Y. Zoological Society, and Mrs. Beebe have returned from an extended expedition for the study and collection of pheasants in eastern countries.

IT is stated in *Nature* that Professor Hans Meyer will undertake in May his fourth journey in East Africa. Starting from Bukoba, on the west shore of Lake Victoria, he proposes to march to Lake Kiva and the Kirunga group of volcanoes, in order to study the relations of the volcanic phenomena to the tectonic structure of the western rift system at this point. From Kiva the expedition will travel by Lake Tanganyika and, if time permits, also to Lake Nyassa. Besides geological studies, the botany, zoology and ethnology of the region traversed will also be investigated.

ON the evening of April 28 Professor Edward L. Nichols, of Cornell University, delivered the annual address before the Iowa Academy of Science on the subject, "The Ends of the Spectrum." Professor Nichols visited the State University of Iowa on April 29, April 30 and May 1. He delivered lectures in the department of physics on recent work in luminescence, and one open to the public on "Daylight."

DR. JOHN M. CLARKE, state geologist and director of science in the New York State Education Department, gave an illustrated lecture before the departments of geology and biology of Colgate University on the evening of May 3. His subject was "The Magdalen Islands and the Bird Rocks."

ON April 13, Professor Heinrich Ries, professor of economic geology, Cornell University, lectured at the University of Alabama on the economic geology of the Canadian northwest.

MR. F. E. MATTHES, of the U. S. Geological Survey, is delivering a course of twelve illustrated lectures with accompanying laboratory work before the students of the University of Michigan, the subject of the lectures being, "Topographic Mapping." On May 3, by invitation of the Michigan Chapter of Sigma Xi, Mr. Matthes told in a popular lecture

"How the Map of the Grand Canyon was made" The maps of the Grand Canyon, Yosemite Valley and the new Glacier National Park have all been prepared by Mr Matthes, who is now engaged upon the map of the new Mt Ranier National Park

SAMUEL CALVIN, professor and head of the department of geology, State University of Iowa, and state geologist of Iowa, died at Iowa City on April 17 He was 71 years of age and had been connected with the University of Iowa for thirty-seven years

PROFESSOR J BOSSCHA, the Dutch physicist, died on April 15, aged seventy-nine years

DR J T THOMPSON, the author of valuable contributions to ophthalmology, died at Cardiff on April 28 He was a brother of Professor Sylvanus T Thompson

THE directors of the New York Public Library announce a gift of $375,000 by Mr Andrew Carnegie to be used for establishing and maintaining a library school

A BILL has been introduced into the legislature of New Jersey providing for the appointment of a state plant pathologist

DR CHARLES A. OLIVER, of Philadelphia, has bequeathed his property valued at $15,000 to the Wills Eye Hospital, the University of Pennsylvania and the College of Physicians of Philadelphia

THE Gray Herbarium, Harvard University, is to have new quarters for its library The structure will be a two-story addition to the present building and will extend to the west, taking the place of the old library wing, and covering part of the site recently occupied by the Asa Gray House, which was removed some weeks ago The addition will be of similar construction to the Kidder wing The library, which will be placed in the new building, is devoted to the classification of flowering plants and ferns It contains more than 20,000 volumes and pamphlets The gift which makes possible the erection of the new building amounts to $25,000, it comes from an anonymous friend of the university.

THE research committee of the National Geographic Society of Washington has made an appropriation of $5,000 for continuing the glacier studies of the two previous years in Alaska The work, beginning in June, 1911, will be done by Professor R S Tarr, of Cornell University, and Professor Lawrence Martin, of the University of Wisconsin, who have directed the National Geographic Society's Alaskan expeditions of 1909 and 1910 in the Yakutat Bay, Prince William Sound, and lower Copper River regions The 1911 expedition will study briefly a number of regions of glaciers not previously investigated by the National Geographic Society, although partially mapped by the Alaska Division of the U S Geological Survey, the Boundary Commissions, etc Work will be done on the present ice tongues and the results of glaciation in the mountains and plateaus of parts of the interior and some of the fiords of southeastern Alaska, the former having lighter rainfall and smaller ice tongues than the Yakutat Bay and Prince William Sound regions

THE Rome correspondent of the London *Times* calls attention to the fact that for some time past Herr Immanuel Friedlander, of Naples, has been working for the establishment in that city of an International Institute to carry on a continuous and systematic investigation of volcanic phenomena An observatory has existed on Vesuvius for many years, but from the insufficient means at its disposal no extended and systematic work has hitherto been possible Such an institute as Herr Friedlander contemplates will be provided with the necessary laboratories and instruments for the regular measurement of temperatures on Vesuvius, for the periodical collection and analysis of the gases, and for the registration and observation of local earthquakes of a volcanic character, not only during the eruptive phases of the volcano, but also throughout its periods of comparative calm It would form a training school for volcanologists, as well as give opportunity for other scientific persons to make observations Herr Friedlander's idea is not a new one An International Institute on Vesuvius was advocated some time ago by Professor Johnston Lavis, Mr Cool, a

Dutch engineer, and Professor Gaetano Platania have also supported the same idea In the opinion of Herr Friedländer, however, it would be better to place the institute in Naples itself, where there would be less danger to the costly laboratories and apparatus, and where the vicinity of the university and other scientific institutes would facilitate the work. After communicating his plan to the last International Geological Congress, held in Stockholm, and obtaining the approval of the congress Herr Friedlander set to work to canvass among the scientific societies of every nation for supporters He has now secured 62 eminent names, among them 25 Italians, 19 Germans and three Englishmen, Sir Archibald Geikie, the president of the Royal Society, Professor H L. Tempest Anderson, of York and Professor H L Bowman, of Oxford The Royal Academy of Naples and the Geological Committee of Italy have given their adherence to the scheme, some 60 of the most prominent scientific and political personages of Italy are forming a committee to promote it, and the Italian government will shortly decide as to what official support can be given also Herr Friedlander has himself generously subscribed £4,000 for the building fund, and another £4,000 to be spread over a term of ten years in ten annual payments The success of the scheme only depends now upon the amount of the subscriptions which will answer Herr Friedlander's appeal to the general public of every country As far as Italy is concerned the scheme has already obtained the full approval of the most important members of the scientific world

It is stated in the London *Times* that the regulations issued by the Belgian government for the prevention and cure of sleeping sickness in the Congo provide heavy penalties for neglect of the prescribed precautions. All employers of native labor must take measures to discover any cases of sleeping sickness among their staff and report them at once to the authorities. Those aiding others to neglect the treatment prescribed will be punished, as well as those who try to pass from infected to uninfected districts or *vice versa* It is noted that in order to combat the disease effectively it is all-important to discover those victims who have not yet reached the second stage—somnolence Such a measure would tend not only to decrease the mortality but also to limit the dissemination of the germs All suspects, therefore, are to be examined by the heads of trading posts or sent for inspection to the nearest doctor, who will carry out a thorough examination. Inspection posts are to be established on the main lines of communication in order to prevent suspects from carrying the disease into provinces which are as yet untouched. Natives from the surrounding countries will only be permitted to enter the unaffected regions of the Belgian colony after undergoing a searching medical examination at Ala or Jakoma

A Conference on Sleeping Sickness has been held at the British Foreign Office as a result of representations made of the danger of the spread of sleeping sickness in consequence of the construction of the Rhodesia-Katanga Railway, which runs from the north of Broken Hill to the Congo frontier and beyond The delegates to the conference were M Melot, representing the Belgian government, Dr van Campenhout, of the Colonial Office in Brussels, Dr Sheffield Neave, representing the Rhodesia-Katanga Railway, Dr Aylmer May, representing the Chartered Company, Dr Bagshawe, of the Sleeping Sickness Bureau, and representatives of the British Foreign and Colonial Offices

A committee for the study of the sea was appointed in 1909 by the Italian Society for Advancement of Science. *Nature* states that its work was so active and promising that the committee was converted by an act of parliament into an institution of the Italian kingdom. The Regio Comitato Talassografico Italiano is to be concerned with investigations of the Italian seas from the physical and chemical points of view as well as from the biological Great importance will be attached to practical questions concerning the navigation and the fisheries. Investigations of the

high atmosphere will also be made in connection with aviation. The president of the committee is the marine minister, and representatives of the chief institutes, academies and societies which take interest in sea investigations have been appointed as members In addition the committee has a scientific staff of its own; it receives a yearly grant from the Italian government of 60,000 lira, and the ships for the cruises are supplied by the Italian navy Four cruises in the Adriatic Sea have taken place already, the program of which was agreed upon with the delegates of the Austrian government, and a fifth cruise will soon start

THE report of the departmental committee appointed to report on the present condition and the future development of the collections comprised in the Science Museum at South Kensington and the Geological Museum in Jermyn-street, has been issued as a parliamentary white paper According to an abstract in the London *Times* the committee finds that the objects now exhibited are so much crowded that their due classification and utilization are impossible Buildings twice the size of those now used would be fully utilized by the existing collections without the addition of a single specimen The committee states that the physics section is hopelessly overcrowded In the motor car and aeronautical groups, both early construction and later developments will require further illustration The electrical engineering section requires to be increased by five or six times its present dimensions. In no section is there more urgent need of early action to secure for the museum examples of instruments and appliances that have marked the opening of a new era in invention and industry. A conference room, where scientific or technical societies might meet, a large lecture theatre, public demonstrations in the galleries, and the exhibition of temporary collections are also suggested. It is recommended that the geological survey offices and library and the Museum of Practical Geology, which are now cramped by the limitations of the building in Jermyn-street, should be grouped, as at present, in a single building, and it would be of great advantage to have that building erected as part of the general scheme at South Kensington If the collections in the Science Museum and in the Jermyn-street Museum were brought together they would provide the basis of a collection that would be complete as regards stratigraphical and economic geology. Such a collection in the new buildings, with the systematic collection of minerals and the paleontological collections in the British Museum (Natural History), would represent at a single center the whole field of geological science In most of the departments of science and its applications, the committee concludes, the museums contain much that is of great historical interest and value They are rich in specimens, instruments, machines and models selected and exhibited in such a manner as to repay systematic examination by the student. *In many sections, however, the* collections are now far below the standard which it is clear they ought to reach in these matters, and their proper organization is impossible in the existing accommodation A science museum in which all branches of physical science, pure and applied, and the scientific and economic work of the geological survey shall be adequately illustrated in close proximity to the other great museums at South Kensington would be of incalculable benefit alike to intellectual progress and to industrial development.

UNIVERSITY AND EDUCATIONAL NEWS

AT the recent session of the Alabama legislature the University of Alabama was given an additional appropriation of $300,000, to be expended during the next quadrennium for maintenance and new buildings.

Two gifts from Mr. Carnegie to the Carnegie Technical Schools were announced last week. On his recent visit to Pittsburgh he presented the schools with a valuable 725-acre tract of land that he had owned for some years at Garver's Ferry, twenty-five miles up the Allegheny River from Pittsburgh It will be converted at once into an experimental

station and engineering camp The other gift was a set of designs by Mr John Wynkoop, made in the École des Beaux Arts of Paris and awarded a medal

THE inauguration of Dr George Edgar Vincent as president of the University of Minnesota will take place October 18 or 19 next The date has been fixed by the fact that the American Association of State Universities will meet at Minnesota on these days

PROFESSOR JAMES R ANGELL, head of the department of psychology and dean of the Senior Colleges, has been chosen by the board of trustees of the University of Chicago to succeed George E Vincent, now president of the University of Minnesota, as dean of the faculties of arts, literature and science

MR GEORGE CHANDLER WHIPPLE, formerly in charge of the biological laboratory of the Boston water department and later of the sanitary work connected with the water supplies of New York City, since 1904 practising sanitary engineer, has been appointed professor of sanitary engineering in the Graduate School of Applied Science of Harvard University

DR ERNEST SACHS, of New York City, has been appointed associate in surgery at the Washington University Medical School, St Louis

IN Stanford University J A Koontz and E G McCann have been made instructors in electrical engineering

DR. H N ALCOCK, London, has been appointed to the chair of physiology in McGill University

DR EMIL ABDERHALDEN, professor of physiology in the Berlin veterinary school, has been called to Halle, to succeed Professor Bernstein, who retires from active service at the close of the present semester

DISCUSSION AND CORRESPONDENCE

THE COMPARATIVE VALUE OF METHODS FOR ESTIMATING FAME

IN a recent contribution upon "Historiometry as an Exact Science"[1] Dr F. A. Woods calls attention to what appears to be a failure of the "space method," as compared with the "adjective method," in solving the problem which I proposed in SCIENCE, October 7, 1910, viz, to determine by purely objective methods the comparative fame of Sophocles and Euripides This apparent failure might seem to support my statement that "historiometry so-called can never aspire to the name of an exact science" were it not for the fact that Dr Woods has not established the superiority of the adjective method in this particular instance For the purpose of illustrating the comparative value of methods for estimating fame I wish to examine the problem of the two Greek poets a little more closely

[1] SCIENCE, April 14, 1911.

Those who are familiar with Greek literature are well aware that Sophocles is superior to Euripides in majesty, grandeur and the various other qualities quoted by Dr Woods from Mr Jebb and the critics But there was one quality, not named by Dr Woods, in which Euripides excelled Sophocles and this one quality more than outweighs the sum of his deficiencies Mrs Browning alludes to this quality in her poem "Wine of Cyprus"

> Our Euripides the human,
>   With his droppings of warm tears,
> And his touches of things common
>   Till they rose to touch the spheres

The humanity of Euripides and "his touches of things common" have appealed to mankind far more than the majesty and ideal art of Sophocles Aristotle states that Sophocles represented the men and women of his dramas as they ought to be, but that Euripides represented them as they actually were It was because he was the first to portray upon the stage the motives and lessons of every-day life that philosophers, statesmen, poets and all other conditions of men have come to prefer the plays of Euripides to those of any other ancient writer.

In comparing Sophocles and Euripides it must be remembered that the latter inaugurated a new epoch and the changes which he

introduced into the drama found disfavor among the Athenians of the old conservative school It was for this reason that Sophocles won five times as many prizes as his younger rival, yet Sophocles himself came to see the significance of the new movement and in his later years began to imitate Euripides

As an influence in human history Sophocles almost sinks into insignificance when compared with Euripides Historians dwell at great length upon this point Curtius in speaking of "this importance of Euripides for the general history of the world" makes the following statement

The real classics, such as Pindar, Æschylus and Sophocles, are only to be thoroughly understood and appreciated by contemporaries, or by those who by study accommodate to them their whole way of thinking Euripides, on the other hand, by the very circumstance that he put an end to the severe style of earlier art, stepped forth from the narrower sphere of the merely popular, he asserted the purely human motives of feeling which find a response in every breast, hence his clearness and intelligibility, hence without presuming any special interest in the subjects derived from mythology or claiming a higher strain upon the intellectual powers, he satisfies the demands which men at all times and in all places make upon the drama He is at once interesting and entertaining, terrific and affecting, he offers a wealth of thoughts and reflections, which come home and are of importance to every one, and is a poet for every educated man who understands the language in which he writes For the same reason, too, he was able to affect the minds of the foremost among his contemporaries, such as Socrates, and the language of the Attic stage, as he developed it, became the standard for the drama For the same reason he also pointed out its path to plastic art, and showed it how it could do new and important things after the age of Phidias, and therefore, though in his lifetime he had been unable to prevail against the still acknowledged tradition of earlier art, he filled the world with his fame after his death, and found numerous followers among the poets, who made use of the Greek myths in order to obtain dramatic effects of universal human significance

This passage from Curtius is of great interest, for it not only illustrates the greater historical importance of Euripides, but it also shows that the ultimate significance of a man's work can not be measured by the prizes or honors which he may receive from contemporaries and that the forces which bring a man fame may go on with far greater intensity after his death than during his life time

In order to illustrate what the historian means when he says that Euripides "satisfies the demands which men at all times and at all places make upon the drama" a few examples may be given

Curtius states that the plays of Euripides accompanied the Athenian traveler by land and sea, so also in modern times when De Quincey started on his wanderings he took with him a pocket volume of Euripides Even Mr Roosevelt, when preparing for his African hunting trip, included in his famous "pigskin library" a copy of this same poet

Lucretius in discussing the indestructibility of matter translates from Euripides, "Nothing that exists can perish, but everything on decomposing takes on a different form", so also in modern times von Lippmann, in the introduction of his "Abhandlungen und Vortrage," hopes that the reader may imbibe the spirit of Euripides, who said, "Happy the man who has gained a knowledge of science"

The Greek poet Ion in his elegy to Euripides reminds him that his fame will endure as long as Homer's, and Dante in his "Divine Comedy" mentions among the shades of departed Greek poets Homer first and then Euripides Dante does not speak of Sophocles in his whole poem, and we can see from this how slight the influence of Sophocles was upon the thought of the middle ages

Seyffert in his "Kulturgeschichte der Griechen und Romer," when discussing the development of the drama, states that "the tragedians following Euripides made him their model and pattern without qualification and the Roman poets preferred paraphrasing his dramas to those of other tragedians" The Roman poet Ennius paraphrased the "Andromeda" and some twenty other tragedies of Euripides, so also we find in more modern times that Racine paraphrases the "Andromache" and other plays, Goethe paraphrases

the "Iphigenia," and Browning the "Alcestis." Racine, Goethe and Browning selected Euripides and not Sophocles for their special purposes, owing to the fact so well stated by Perrin that Euripides comes nearer to the modern heart than Sophocles or any other ancient poet. The best testimony upon this point, however, is that of Racine himself, who, writing in 1676 in the preface to his "Iphigenia," expresses his indebtedness to Euripides as follows

> As regards the portrayal of the passions I have endeavored to follow Euripides most exactly I confess that I owe to him a large number of the passages which have been most praised in my tragedy I have seen with pleasure, from the effect which my imitations of Homer and Euripides have produced upon our audiences, that good sense and judgment are the same in all ages The taste of Paris conforms to that of Athens My audiences have been moved by the same things which once moved to tears the most intelligent people of Greece and which made them say that among the poets Euripides was the most tragic of all, that is to say he knew how to excite to a marvellous degree the feelings of pity and fear, which are the true ends of tragedy

It is probable that Euripides through his "Iphigenia" alone has exerted a greater influence upon modern thought and feeling than Sophocles with all his plays combined Erasmus in 1524 translated the "Iphigenia" from Greek into Latin, Dolce gave an Italian rendering in 1560; Sibilet (1549), Rotrou (1640), Racine (1674), Leclerc and Coras (1675) gave different French imitations; many English versions were given in the eighteenth century, Goethe's "Iphigenia" was completed in 1787, Gluck's opera upon the "Iphigenia" was produced in 1774 and since his time over twenty other composers have set music to the same theme. The recent revival of interest in the "Iphigenia" through the choral dances of Miss Duncan is well shown by the increased demand for this and other plays of Euripides at book stores and libraries.

Many other examples might be given to illustrate the much greater historical importance of Euripides as compared with Sophocles, but enough has been produced to show that as regards the special purposes for which mankind at large read, consult, quote, paraphrase or otherwise make use of a poet Euripides has always been preferred to Sophocles. And the approximate ratio of this preference, according to the five objective methods employed in my previous paper, is over 2·1.

The failure of the adjective method to give a verdict agreeing with that so unmistakably expressed by history and by mankind at large is very evident The adjective method—by which is meant the ratio of the number of adjectives of praise against those of dispraise—neglects to give the specific value of the terms, human, sublime, artistic, etc, the summation of which is supposed to constitute fame. The ratio of mere numbers gives each qualifying adjective the same value, when perhaps the number of adjectives expressing humanity and feeling should be raised to the tenth power and those expressing majesty and art only to the second power

The mathematical formula for expressing fame (F) in the terms of its components a, b, c, etc, is not $F = a + b + c$, but $F = x\,a + y\,b + z\,c$, in which x, y, z, etc, are unknown and indeterminate functions. That historiometry can never become an exact science is evident from the fact that the values which men give these unknown historiometric functions are different in different ages, races and individuals The twentieth-century mind would lay more stress upon the scientific, the medieval mind upon the mystical; the Roman would lay more stress upon the legal, the Greek upon the beautiful; the clergyman would lay more stress upon the ideal, the business man upon the practical Until historiometry can develop a set of functions whose values shall be constant for all men in all ages it must remain among the most inexact of sciences.

Another objection to the adjective method is that fame is not a mere summation of eulogistic attributes. Napoleon, for example, heads Professor Cattell's well-known list[3] of 1,000 eminent men, in connection with which list its author makes the following statement:

[3] *Pop. Science Monthly*, February, 1903, p. 362.

"There is no doubt but that Napoleon is the most eminent man who has ever lived, yet it should give us pause to think that this Titan of Anarchy stands first in the thoughts of most men." In the passage just quoted we have one extremely eulogistic phrase "most eminent man" counterbalanced by another phrase of extreme disparagement "Titan of Anarchy." A similar array of favorable and unfavorable expressions can be found in any impartial biography of Napoleon It is this peculiar blending in one man of different extremes which has given Napoleon and many other men a great share of their celebrity; in such cases the ratio of the numbers of adjectives of praise against those of dispraise fails to give a true answer to the question, which man of a given group of men is the most eminent or historically most important

The space method and reference frequency methods of estimating fame are not open to the objections which have been raised against the adjective method The historian in discussing, for example, the respective influence of Euripides and Sophocles upon human affairs must necessarily devote more space and make more references to Euripides since his influence in this respect was much the greater, yet in doing this he need not necessarily employ any adjectives of direct praise or dispraise

The space method and reference frequency methods are also more free from the errors of personal equation than the adjective method In the sentence "Cæsar was ambitious" one person might regard ambitious as a term of praise and another of dispraise, yet these two persons would agree perfectly as to the number of lines in a biographical sketch of Cæsar or as to the number of times Cæsar was referred to in an index

In the selection of a method for estimating historical values it would seem then necessary first of all to dissociate the question of merit from that of fame, and the questions of excellence in particular directions from the broader questions of historical importance For estimating merit and excellence in particular qualities, which is perhaps the chief concern of the critic, the adjective method proposed by Dr. Woods may possess certain advantages But for estimating fame and historical importance, which is the chief concern of the "historiometrician," the adjective method would seem far inferior to the space and reference frequency methods.

As to the exactness of historiometry as a science, may we not say what Huxley once said of another science, the most exact of all. It "grinds your stuff of any degree of fineness, but nevertheless what you get out depends on what you put in"

C A. BROWNE

NEW YORK CITY

DR. WOODS'S APPLICATION OF THE HISTOMETRIC METHOD

THE paper by Dr F A Woods, published in SCIENCE, April 14, giving the results of his metrical investigation of the biographies of eminent Americans is one of great interest. Both in method and results it opens fields of investigation of the highest sociological value He has proved the reliability of his figures by reaching approximately the same results, for the state of Massachusetts and the other thirteen original states, when using different sets of data, and while the variation in the results indicate what would be considered in physics as a large probable error, yet they are really small considering the method used and the number of observations

If the wide range shown thus by the different states in their production of eminent persons per thousand of their white population can not be explained by environment it is evident that the arguments for the dominance of hereditary ability will be strongly supported On the other hand, if it can be explained by a high coefficient of skew correlation with one or more series of quantities expressing any antecedent social condition it leaves just so much less for heredity to explain Thanks to the work of Galton and others, heredity is already mathematically expressed by the correlation of the characters of individuals in successive generations. And perhaps for that reason the tendency now is to exaggerate the

relative importance of heredity Dr Woods himself, judging from his article in *The Popular Science Monthly*, April, 1910, has taken an extreme view of the dominance of heredity over environment, and apparently he expects the present investigation to support that view The further publication of his results will therefore be awaited with special interest

The first series of quantities expressing environment in youth which is suggested for correlation with the percentage of eminence in maturity is educational The simplest measure of educational opportunity in each state is its expenditure per capita for school purposes We do not know the average per annum, but we do know, accurately for most of the states, the public expenditure forty years ago for the education of the present generation These data are given in Table 14 of the Report of the Commissioner of Education for the year 1910 For a first approximation we can assume that the ratio of per capita expense in the different states has been constant, and it is only with the ratio that we are concerned

Massachusetts stands highest with $3 73 per capita, which was more than twice the average of the whole country, and also more than twice the average of the thirteen states Dr Woods has tabulated. Connecticut is second with $2 74 New Hampshire stands near the average But it is well known that private educational institutions are relatively more important in New England than in any other part of the country, while Harvard and Yale colleges would substantially raise the preeminence of Massachusetts, Connecticut, and the whole group, in the total per capita expense table, and so give them the places they have in Dr Woods's table

Virginia, which Dr. Woods found to be generally below the average in the table of eminence, is credited with only 47 cents in the expense table But including West Virginia, which was not separated until 1863, the average was 86 cents

South Carolina, which Dr Woods found to be slightly above the average for the white population, is credited with only 38 cents per capita of the whole population But that state had the highest percentage of colored population (60 per cent in 1870), while forty years ago most of the school money was spent on the white schools, and in ante-bellum days of course it was all for the white population. This would raise the per capita expense to 95 cents, and give it good rank among the southern states, but still below the average of the thirteen states Why this state should stand above the average in Dr Woods's table remains to be explained It shows, as we should expect, that schools do not supply all of a child's environment, and other correlations must be sought—the ratio of whose coefficients ought to be significant of their relative importance in making eminent persons

North Carolina, which Dr Woods found "has always had the worst record" for the production of eminence, the percentage being about one-fourth the average, is credited with only 16 cents per capita for education—this being the lowest for the thirteen states, and also for the whole country—being in fact about one tenth the average But applying the same total expenditure to the white population the per capita expense would be 25 cents —about one sixth the average

The average number of days of public schooling given to each inhabitant between the ages of five and eighteen years, in the school year 1870–71, in the New England and middle states was 70 2 days, and in the southern Atlantic states only 18 1 days The per capita expense therefor was $2 38 and 63 cents, respectively

We seem to be near the time when the cost of encyclopedic eminence can be stated in dollars without making any reflection on the compilers of those works.

Further, if we can approximate the expense of higher as well as elementary education in each state, we can easily, by the method of least squares, determine the ratio between them which is most favorable for the production of eminent persons

It appears that Dr Woods has directly opened the way to the mathematical determination of the relative importance of hered-

ity and environment At least we may expect a flood of new light on the subject from historical investigations, and if the conclusion is different from what the author of the method anticipated it will not at all detract from the credit due him for its development

BROOKLYN, N Y

METALS ON METALS, WET

TO THE EDITOR OF SCIENCE A year or two ago I repeated to a class in elementary physics the statement, familiar to generations of engineers on the authority of General Morin, supported by the approval of Rankine, that the coefficient of friction of *metals on metals, wet*, is considerably greater than that of *metals on metals, dry*

Thereupon a thoughtful youth in the class asked me why, if this were the case, it was customary to put sand on wet car-rails to prevent the slipping of the driving-wheels Taken aback by this unexpected scepticism, I begged for time to find the right answer to the disturbing question and set to work experimentally on the problem The student reported after a time that trackmen had told him the water they had trouble with was usually slimy, which seemed to be a fairly satisfactory explanation of the puzzle, but meanwhile my experiments had shown some interesting facts, which I will here set forth

Using a disk of brass, about 7 5 cm in diameter and about 0 6 cm thick, on a flat brass plate, I found.

1 That, when there was no load on the disk, a few small drops of water placed between it and the plate multiplied by a factor which might be as great as 3 the friction between the two.

2 That, when the disk was heavily loaded, the presence of the few small drops of water between it and the plate made little, if any, relative difference in the friction between the two.

3 That when plenty of water was used, so that it covered the whole space beneath the disk and extended somewhat beyond the edge, the disk without load was drawn along the plate quite as easily, apparently, as when both were dry

From these facts I came to the conclusion that the increase of friction observed in case 1 was not due to an increase in the *coefficient* of friction caused by the water, but merely to the increase of pressure between the disk and the plate, caused by the suction of the capillary perimeters of the water-spots between them When there is much water its perimeter is outside the edge of the disk, is wide, or thick, and has little effect

Some little search in books dealing with the subject of friction has failed to show there any recognition of this possible explanation, and refutation, of the Morin-Rankine statement of the large value of the coefficient for *metals on metals, wet*, but I should hardly have written you about the matter if I had not recently found this statement repeated in the "Smithsonian Physical Tables" published in 1903 I hope the new edition of these tables will not quote Rankine on this particular without further evidence

SCIENTIFIC BOOKS

The Stability of Truth By DAVID STARR JORDAN New York, Henry Holt & Co 1911 Pp 180

"This little book," says the author, "represents the substance of a course of lectures delivered on the John Calvin McNair foundation in the University of North Carolina, January, 1910"

The chapter headings are· Reality and Science, Reality and the Conduct of Life, Reality and Monoism, Reality and Illusion, Reality and Education, Reality and Tradition.

Evidently something has happened in philosophy, in science or in both when a scientist of the first class, not to say the author of this volume in particular, puts out a book with the good old philosophical term, "Reality" at the head of every chapter Doubtless in the minds of most scientists there will be little question about where "something has happened"

They will say that philosophy has at last discovered that neither its problems nor its methods are so fundamentally different from those of science as was once supposed, that there is now a great philosophical movement, with an evolutionary logic—the conception of the working hypothesis—as its avowed method, and that it is therefore now possible for a scientist to stroll into the field of philosophy and set to work with his own tools. And indeed the spirit of this philosophical movement variously known as "pragmatism," "evolutionism" and "experimentalism," is certainly very different from the Hegelian idealism, which found the difference between philosophy and science to consist in the fact that the doctrines of the former are "necessary," while those of science are merely "hypothetical."

Still, in such a *rapprochement* as is taking place between philosophy and science it would be strange if all the change were on one side. For one thing, it seems obvious that the surrender of absolutistic methods by philosophy means added responsibilities for scientific method. Under the old régime science, even while renouncing and denouncing philosophy and all its works, found comfort in turning over to philosophy certain ethical and social questions which it found difficult to handle or which interfered with the pursuit of "purely scientific truth."

Much of the doctrine of this book (whose title, by the way, means that the only truth that is stable is that truth is not stable) is to the effect that if important human interests formerly turned over to transcendental methods are now thrown back upon scientific method, this method must be human enough to take care of them. And this means that scientific method and interest can not be purely intellectualistic. The author says:

> The purpose of this book is to set forth the doctrine that the final test of truth is found in trusting our lives to it. . . The primal impulse, as well as the final purpose of science is the conduct of life. . . . Pure science can not be separated from applied science. . . . Knowledge is power; power is evidence that our belief is knowledge.

These and other similar statements on almost any page warrant the reader in saying that the book points at the hyper-intellectualism of science no less than at that of philosophy.

From the specific doctrines of the book the following points have been specially noted: (1) The recognition, rather unusual in a natural scientist, of the social character of consciousness and the self. "I think, therefore I am, gives place to we think, therefore we are." (2) Mr. Balfour's philosophic doubt is well hit off as "a process by which men question the only things they know to be true in order to prove the reality of things they know not to be true." This applies to all "transcendental doubt." (3) The "recrudescence of superstition," which accompanies an age of science, "is made possible by the fact that the traditions of science are so diffused in the community at large that fools find it safe to defy them." (4) Superstition and dogmatism are shown to be identical in so far as both ignore the process of experimentation. (5) The chapter on Reality and Monism, which is one of the best, puts two questions to Haeckel's monism. Is it a genuine scientific hypothesis, that is, one capable of verification? Is it of any ethical significance in the conduct of life? The author finds for the negative in both cases. (6) In the last chapter on Reality and Tradition, the "warfare between science and theology" is found to be quite as much a warfare between old and new science and to exist in the individual mind of the scientist and theologian alike.

In view of the general insistence upon the organic connection between science and the conduct of life, some readers may find difficulty with certain passages on "Belief," in which belief is justified as a "philosophical" category by "its effect on the conduct of life," even though it "is not reducible to terms of human experience" (pp. 42, 44). But "as men of science," we can not accept any hypothetic "articles of faith" not resting on "scientific induction." "I ought not to say I believe when I can not say I know" (p.

86). Some may take this to mean that "the conduct of life" may still be considered (*e g*, ethically or "philosophically") apart from science, and, conversely, that science may still have an aspect (*e g*, the pursuit of truth) that is independent of the conduct of life

The author's captivating style is too well known to call for comment The publishers have given the book a very attractive form

A W MOORE

Allen's Commercial Organic Analysis Volume IV, Resins, India-rubber, Gutta-percha and Essential Oils Philadelphia, P. Blakiston's Son and Co Pp viii + 466. $5.00 net

The subjects covered in this volume are Resins, by M Bennett Blackler, India-rubber, Rubber Substitutes and Gutta-Percha, by E W. Lewis, Hydrocarbons of Essential Oils, by T. Martin Lowry, Ketones of Essential Oils, by T. Martin Lowry, Volatile or Essential Oils, by Ernest C Parry, Special Characters of Essential Oils, by Henry Leffmann and Charles H LaWall.

As with the previous volumes of the series, the book contains a very large amount of detailed information which is very valuable for any one who has occasion to work with the great number of organic compounds which are used in industry The preparation of the successive chapters by chemists who have expert knowledge of the subjects of which they write insures accuracy and a wealth of information which it would be impossible to secure in any other way

THE QUIZ DEMONSTRATION SYSTEM OF TEACHING QUALITATIVE ANALYSIS

It is time that we are awakening to the fact, that in the line of elementary laboratory work there is altogether too much poor impartation of knowledge. This is particularly the case as regards general chemistry and qualitative analysis, especially when considered from the standpoint of those who expect to carry on their life work in the field of engineering and industrial chemistry.

Qualitative analysis is especially subject to error. Who would think of trusting to a civil engineer, ignorant of the strength of the material employed, the construction of a bridge? Or one's child to a doctor, if cognizant of the fact that he did not know the properties of the drug he was administering? Is it not of as great import to a chemist that he understand the properties of the chemical elements, the material he is using in his daily work?

This being true, why is it that the laboratory instruction is, in many cases, left to assistants paid the munificent sum of from $200 to $500 per year, with, consequently, very indifferent instruction? If they are the best the institution can afford, the fault can be remedied, in part, by the man in charge giving to his assistants all the instruction within his power.

Detail laboratory instruction is the hardest of work, if rightly given, as difficult as any quiz or demonstration, for what is it, if properly conducted, but one continual individual quiz and demonstration of from two to three hours' duration? It is common to consider from two to three laboratory hours as equivalent to one lecture or quiz hour. This is a mistake, at least as far as the instructor is concerned, for it is not a greater impossibility for a man to lecture or quiz for half a day at a time, day in and day out, than for him to give the best that is in him to a laboratory class extending over a like period. I hear some one reply that it takes more time to prepare for a lecture or quiz than for a laboratory period. Granted, when the laboratory work is conducted as is most customary. But when the instructor keeps abreast of the times, makes a *thorough* test of the new methods, keeps track of and endeavors to overcome the difficulties of the ordinary class in qualitative analysis, he will devote much more time to the preparation of his work than a language teacher, for instance, who, year after year, employs the same text in class work. You see I am not making the statement, "He does this," but that he should. This is, of course, not possible when the hours of labor are too many to allow for it the requisite time. They should be shortened. There should be a certain amount of time spent by the instructor in his laboratory "doing things." A German teacher must know how to read the language. To teach laboratory work correctly a man must be able to do the work well himself.

Inasmuch as I am desirous of suggestions and criticisms from my fellow instructors, an underlying, selfish motive prompts me to present the scheme for laboratory instruction employed by me. It is one which I have successfully made use of during the past three years and I feel it a step in advance of the methods heretofore used by me, and of those which I have seen employed elsewhere.

Chemical theory is based on facts obtained in the laboratory. It is then true, that for a thorough comprehension of the theory it is necessary that the student be conversant with the facts before he can understand the application. I proceed, therefore, with this in view, as my main objective point.

As an essential, the instructor must see every test made by the student. That this may be accomplished the too often "drifting" about the laboratory by the instructor must be done away with. There must be system. There must be known, to some one in charge, what is going on in every part of the laboratory. Yet in this system, two things must be guarded against in the student. First, lack of independence. Second, useless waste of time.

with consequent disheartenment and lack of interest in the work

In considering Group I, consisting of lead, silver and mercury, the student is given a typewritten sheet of reactions to perform These are carefully selected to bring out the properties of the elements, especially those which are of most importance in qualitative and quantitative analysis At the completion of the experiments on silver or on silver and lead, in place of throwing out the contents of his test-tubes, the student takes them to the instructor in charge, and the latter, a man of experience, after examining the work carefully, gives him a thorough quiz on it If this work, as well as the student's knowledge of the reactions, etc, is satisfactory, the instructor places his O K upon the sheet If neither the quiz has been passed in a creditable manner nor the student been able to obtain the correct reactions, the contents of the test-tubes are thrown out and the work repeated. After a second trial, if the experiment is still unsuccessful, the instructor should demonstrate it By this means the student is taught independence, there is created in him ability to do things for himself, the instructor is enabled to "keep tab" on the work accomplished, knows if the student has obtained the correct result and yet does not allow him to spend an undue amount of time on something which it is clear he does not understand

This quiz demonstration system is varied to suit the needs of the individual These, the instructor, coming in personal contact with each student as he does, soon comes to know

Before the younger men of the force are allowed to quiz, they should observe the methods of the instructor in charge and then be subject to his direct supervision from time to time, when they themselves are quizzing Thus, in as far as is possible, the policy of the laboratory is uniform and at the same time consistent with the individuality of the persons in question

Upon completion of the preliminary work upon a particular group, the separation of the included elements is studied in a similar manner When the results of this work have received the O K of the instructor the student is given a number of simple unknowns on this group I find that by requiring that he do two of these for every one upon which he makes a mistake, his mistakes become fewer in number and his confidence in his ability thereby increases In taking up the second and following groups, the separations and preliminary work are treated similarly to group one, except that when time is available one of the unknowns is made to contain one or more of the elements of the preceding group In this way the separation of the various groups may be quizzed over as in the separation of each group

The groups and acids take up somewhat over one half the time allotted to the course Then come the general unknowns, where the work of the student is expected to be carried on independently Several simple mixtures are first given, that the student may better connect the group separations In these both the metal and acid are identified Then follow a number of commercial products, consisting of minerals, slags, alloys, etc, the selection being governed, to a certain extent, by the particular field which the student is likely to enter In this district mining interests are of most importance, hence, ores, minerals, slags, etc, make up this portion of the course

Individual quizzing on this part of the work is not as frequent as before, but when reporting an unknown, the student is quizzed on reactions, method of separation, identification, etc Here class-room quizzing is of more value and can be advantageously used to supplement part of the work with the individual, for, provided he be properly trained in the power of observation, a great amount of knowledge can be gleaned by the student from the mistakes of others, brought to his notice by this group questioning.

At this point too much stress can not be laid upon the exceptions to the general rules and the reason for each step taken in the separation. Herein is differentiated the training of the professional from the routine chemist. I find, also, at this point in the training, of the

utmost importance, and yet one of the greatest difficulties encountered, is the mastery of the proper method of disintegration, especially of the insoluble substances and those which are likely to lose part of their content by volatilization. If a proper solution of the unknown is obtained, the analysis is comparatively easy, whereas, if not obtained, incorrect results are sure to follow. Alloys and metallurgical products containing relatively small amounts of some one substance also require special attention.

Objections have been raised to the use of technical products for unknowns, claiming that they do not give the proper amount of training. This is apt to be true where unknowns of a commercial nature are taken just as they come to hand without special effort on the part of the instructor. It is certainly not the case if care is taken in obtaining what is necessary to suit the problem in question, for there are certainly sufficient varieties of commercial products to cover the field. Aside from giving the students a training not to be had in the use of laboratory prepared unknowns, his interest is much more easily aroused and held when he can see something "practical" in what he is doing.

I have found that where lectures are combined not alone with class-room quizzing but as well with this demonstration method the student is made to think and gets a grasp on the subject well worth the time spent in its acquisition.

RAYMOND C. BENNER
UNIVERSITY OF ARIZONA,
TUCSON, ARIZ.

HUMUS IN DRY-LAND FARMING

It has been the consensus of agricultural opinion and experience, both in this country and in Europe, that the production of wheat on the same land year after year results in steadily decreasing yields. Chemical investigations in several instances have shown this decrease in yield to be accompanied by a correlated decrease in the supply of humus and of nitrogen in the soil. Under the title of "The Nitrogen and Humus Problem in Dry-Land Farming," Mr. Robert Stewart, chemist of the Utah State Experiment Station, has recently published the results of some investigations with special reference to the effect of continued wheat growing on the non-irrigated lands of the Cache Valley in Utah.[1]

Mr. Stewart's investigations in the Cache Valley indicate that the continuous production of wheat in that section has not resulted in a reduction of either the humus or the nitrogen supply of the soil, at least during the thirty years or more that wheat has been so grown there. He finds, indeed, that in something over twenty cases where comparisons were possible between virgin soil and soil that had been cropped to wheat for several years there has been a slight increase, both in the total nitrogen and the humus in the surface foot. In the second foot of soil on these two sets of fields he finds a decrease of the total nitrogen on the cropped land, but a marked increase in the humus. His summary of results shows that on the wheat land there has been a 10 per cent. increase in the humus supply of the surface foot and a 25 per cent. increase in the second foot.

Mr. Stewart wisely avoids any generalizations upon the limited data he presents in this publication. But it is unfortunate that he does not give more consideration to the agricultural conditions and farming methods that prevail in the region of which he writes. Unless the reader of Mr. Stewart's bulletin is familiar with conditions in the Cache Valley, the results presented are likely to seem either pointless or irreconcilable with the results of similar investigations elsewhere. To one who knows those conditions, the brief statement that "Some of the farms of this district have been under cultivation for forty-five years, and apparently yield as good crops as they ever did" may seem to be a good and sufficient epitome of the situation; but if one does not know the region, this sentence hardly seems adequate.

It is true that accurate data as to the farm yields for past years are difficult to obtain and

[1] Utah Agricultural College Experiment Station Bulletin, No. 109, August, 1910.

are unsatisfactory to use, because of the uncertain factor of variable climatic conditions from year to year; but some comparisons might have been made between the yields obtained during recent years from land that has long grown wheat and the yields on virgin or nearly new fields on similar soils. Or, lacking such data, it would have been helpful to the reader had there been given some statement as to the present wheat yielding capacity of the fields from which the samples were obtained.

Unless it is shown definitely that the maintenance of the nitrogen and humus content of these Cache Valley soils is correlated with the maintenance of their wheat yielding capacity, these investigations lose much of their possible value.

As to the matter of the farming methods for wheat production on this Cache Valley land, it is the general practise to harvest the grain with a header or with a combined harvester and thresher, either of which implements leaves on the land the major portion of the grain straw, which is subsequently plowed under.[3] Mr. Stewart makes incidental reference to this feature of the agricultural practise in the Cache Valley, but he does not make it clear that in this respect that practise is essentially different from what it is in the dry-land wheat regions of the Great Plains and eastward, where it is the custom to harvest the grain with a binder and remove the larger part of the straw. This omission seems particularly unfortunate, in view of the general, and possibly misleading, inferences that may be drawn from Mr. Stewart's otherwise valuable contribution to knowledge. If, as it seems reasonable to believe, the true explanation of the observed humus maintenance lies in the practise of plowing under each year the large amount of wheat straw, it becomes apparent that similar results are not to be expected where a similar practise is not followed.

SOME EXPERIMENTS ON THE PRODUCTION OF MUTANTS IN DROSOPHILA

MACDOUGALL has reported the successful production of mutations by treating the ovaries of certain plants chemically or osmotically. As long as the full account of his results is not available, it is not easy to judge to what extent it is possible to produce mutations at desire with his method. Tower has apparently succeeded in producing in various species of *Leptinotarsa* certain color mutations at desire by submitting the beetles, during the period of the growth of the eggs, to different degrees of temperature and moisture from those in which they usually live. Gager mentions that by treating the pollen or ovaries of *Œnothera* with radium, some of the new plants were entirely different from the mother plant. Morgan has published the statement that a number of the interesting mutations of *Drosophila*, which he has recently described, came from a culture which had been treated with radium.

The following experiments were undertaken for the purpose of forming a conception concerning the degree of certainty with which mutations can be produced experimentally. We tried the effects of a constant and comparatively high temperature, of radium and of Röntgen rays. The stock of *Drosophila* which we used in these experiments was given us kindly by Dr. Lutz, to whom we wish to express our thanks.

1. *Effects of High Temperature.*—Several culture dishes with *Drosophila* were put into a thermostat, the temperature of which remained constant within 1° around 30.5° C. We found that at higher temperatures we lost a large number of cultures. In the fifth generation of flies, kept in the thermostat, on February 16, a number of dark flies appeared. They were mated with normal ones of the same culture. Some of these cultures were kept in the thermostat and others were brought into room temperature, to see whether at a lower temperature they would continue to breed true. This has now been the case for five

generations Darkness is recessive to the normal yellow and is not sex limited Our dark mutation is possibly identical with Morgan's "melanotic" mutant

On the seventh of March we began to repeat this experiment with the necessary control at room temperature On April 10, we found in the first filial generation of the control culture kept at normal temperature a dark specimen None of eleven new cultures kept in the thermostat have thus far given rise to a dark or any other type of mutant Since then dark individuals were found in another control culture

From these experiments we must draw the conclusion that a constant temperature of 30 5° does not necessarily produce mutations in *Drosophila,* and second, that a dark form of *Drosophila* may arise "spontaneously," that means by forces at present unknown

2. *Experiments with Radium*—A very large number of experiments with radium were undertaken, because it happened that the first culture which we treated with radium chanced to give us mutants We succeeded in producing short-winged specimens in two different cultures by treating them with radium, while thus far we have not yet observed this mutation in cultures not treated with radium The manner of appearance of this short-winged mutation was in both cases the same In the second filial generation of the flies treated with radium, one or more short-winged males appeared The various forms of mating were tried and yielded the result that the short-winged condition is a sex-limited character The wild normal males were found to be heterozygous in regard to short wingedness Thus our short-winged mutant behaved like, and is probably identical with the "miniature"-winged mutant discovered by Morgan. We have now bred the short-winged males and females for five generations and find that they remain constant

We expected that we might succeed in producing short-winged mutants at desire, but in this we failed Although we treated more than two hundred different cultures with radium we only observed the appearance of the short-winged mutation in the two cultures, although we repeated the conditions of our successful experiments quite frequently In both successful cases we submitted the animals only for one or two hours to the action of radium In one of the two cases the newly-hatched imago alone, males and females were treated for two hours with a weak radium preparation (10,000 units) which was coated with collodium It is possible that the alpha rays may have affected the animals In the second successful case a strong radium bromide preparation (over 1,000,000 units) in a glass tube was applied for one hour to a mixture of imago, eggs and young larvæ

In five different cultures of flies treated with radium the dark mutation appeared, but, while the short-winged mutants appeared in both cases in the second filial generation, there was no regularity in regard to the appearance of the dark mutants

In one culture treated with radium a white-eyed female appeared in the first filial generation, it is possible that the existence of a white-eyed male in a previous generation may have escaped our notice In two radium cultures we observed the pink-eyed mutants, but this was also found in cultures not treated with radium

3 *Experiments with Rontgen Rays* have given us thus far no mutants

Our results can be summarized as follows:

1 A large number of cultures of *Drosophila* were treated with high and constant temperature, with radium, and with Rontgen rays Four types of mutations were observed, a dark form (which was the most common), a pink-eyed, white-eyed and short-winged form.

2 In the control cultures, which had not been treated, the dark and the pink-eyed mutations were also observed. As far as the white-eyed mutation is concerned, it is probable that it originated before the treatment of the culture with radium

3 The short-winged mutants have appeared thus far only in the cultures treated with radium, namely in two cultures out of several hundred We did not succeed in producing the short-winged mutation at desire by treat-

ing the cultures with radium

We wish to express our thanks to Mr Berlinicke, of the firm of Hugo Lieber & Co, who was kind enough to loan us the radium used in these experiments, and to Mr Bagg, who assisted us in our observations

JACQUES LOEB
F W BANCROFT

ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH

AN EXPERIMENT IN DOUBLE MATING

IN my "Inheritance in Silkworms, I," (1908)[1] I called attention (pp 37–39) to the beginnings of an experiment in double mating Only the F_1 generations following a few matings had been obtained at that time, but they gave such promise of interest that I determined to continue the experiment and to widen it I have now in hand the notes on 85 silkworm broods belonging to this double mating experiment series of 1910 Some of these broods are the F_4 generation from the original 1907 double matings, while others are F_3 or F_2 generations from the original 1908 or 1909 double matings Taken together the notes of these various 1907–10 rearings from double matings are sufficient to pose some suggestive queries

By the double mating of silkworms I mean the mating of a female of one race with two males representing different races, one of them usually of the same race of the female, the other of another race Races are chosen which are readily distinguished by a difference in cocoon color, as yellow or white, or in larval pattern, as banded and unbanded The silkworm is polygamous and polyandrous, both males and females usually mating more than once before egg-laying begins Or this repeated mating may continue after egg-laying has begun.

Moths to be experimentally double-mated are reared from carefully isolated cocoons, and the two matings are made to take place immediately following one another for equal or definitely determined unequal periods of coupling, and always before any egg-laying by the female The young produced from the eggs of each double-mated female are reared isolated in separate trays, which are covered over during the later laryal life (possible straggling time)

In any consideration of the results of such repeated mating the unusual way in which the eggs of insects (at least of the silkworm moth and hosts of others) are fertilized must be remembered This way is, simply, that the male fertilizing cells, the spermatozoa, are received by the female at mating into a special sac or receptacle, the spermatheca (there may be several spermathecæ, as in flies) in which the spermatozoa remain alive and active This spermatheca, a diverticulum of the oviduct, is situated near its external opening, the vagina As the unfertilized eggs of the moth pass slowly down from the ovarial tubes into the oviduct they lack only fertilization to be entirely ready for development They have already their full supply of yolk, they are already enclosed in their protecting envelopes (vitelline membrane and outer, firmer chorion) But these envelopes do not completely enclose the egg-mass, there is, at one pole of the egg, one or more small openings, the micropyle, through which the spermatozoa, issuing from the duct of the spermatheca as the eggs pass, enter the eggs As soon as a single spermatozoan has entered, a jelly-like substance closes the micropyle and prevents polyfertilization

Thus when the silkworm moth first mates she receives in her spermatheca, and holds there, a considerable number of spermatozoa representing the heritable characters of the male involved When she couples again she receives another lot of spermatozoa, and if the second coupling is with a male of different race from the first these spermatozoa represent a new set of characters. What is going to be the result of this double mating as exhibited in the offspring?

It seems, at first thought, that this result

[1] "Inheritance in Silkworms, I," *Leland Stanford Junior University Publications*, University Series, No 1, 89 pp, 4 plates, 2 text figs, 1908 Address Librarian, Stanford University, California

should be nothing new, nothing surprising We know already what to expect in any simple mating of different races of silkworms As regards larval pattern and cocoon color the inheritance behavior is usually Mendelian "Moricaud" (all dark) larval pattern is dominant over "tiger," or banded, pattern, banded pattern is dominant over unbanded (all light) Yellow cocoon color is dominant over white And the relation of dominant and recessive is of the usual Mendelian character in F_1, F_2, F_3 and succeeding generations Now although there are two kinds (two races representing these alternative larval and pupal characters) of spermatozoa in the spermatheca of double-mated females, presumably but one spermatozoid finds its way into the egg, and fuses its nuclear matter with the egg nucleus That is, the female, although double-mated, is presumably only single-fertilized.

As a matter of fact the inheritance behavior of the F_1 and succeeding generations derived from these double-mated females does not seem to bear out the simple presumption just stated. The presence in the body (spermatheca) of the female of two kinds of spermatozoa seems to disturb matters The comfortable simplicity and regularity of Mendelian inheritance fails to maintain itself The troubles of irregularity which have not been wholly wanting even in single mating silkworm experiments—and which I have termed in my account of several years' experience of these matings, "strain and individual idiosyncrasies," a term not looked on with favor by thorough-going Mendelians—these irregularities are accented in the double-mating experiments. The irregularities indeed almost assume a seeming of regularity, a non-Mendelian regularity, if such a heresy is admissible

I shall not try to give here the full data of my 85 "double-mating" lots of 1910. But I shall give a considerable number of examples and a general statement of these results. Later, if worth while, all the data can be given; together, I may add, with the results of three or four years' more work in single-mating crossings to test further the inheritance of certain egg, larval and cocoon characters, already pretty fairly determined by the original series of several years whose results have been published

I shall limit the examples referred to in this paper to matings among three races and shall refer only to cocoon characters. The three races are Istrian Yellow, a strong Austrian race producing large golden yellow cocoons, French Yellow, a race producing smaller, salmon yellow cocoons, and Bagdad White, a Turkish race producing large pure white cocoons Bagdad White is a race whose white cocoon color, instead of being regularly recessive to yellow in crossings with yellow cocooning races, is sometimes dominant, as I have shown in my 1908 report (pp 24–25, section on "strain and individual idiosyncrasies") All these races have been bred as pure races by me for the last ten years, that is, races faithfully transmitting certain larval and cocoon characters

In 1908 a Bagdad White female was mated with a French Yellow male from 9 55 A.M. to 11 55 A.M and with a Bagdad White male from 11 55 A.M to 1 55 P.M. The young, reared in 1908, were all white cocooners One mating (1908) (single) among these young produced (1909) 111 white cocoons and 44 yellow cocoons, another produced all white cocoons; also another produced all white cocoons A mating (1909) between two white cocooners out of the 111 white and 44 yellow lot, produced (1910) all white cocoons A mating of two yellow cocooners produced (1910) 8 white cocoons and 40 yellow cocoons, another produced 9 white cocoons and 29 yellow cocoons. A mating (1908) between two white cocooners of one of the all white cocoon lots produced (1909) all white cocoons, and so did another. A mating (1909) of two white cocooners of one of these all white cocoon lots produced (1910) 15 white cocoons and 2 yellow cocoons (sick lot); another produced all white cocoons. A mating (1909) of two white cocooners from the other all white cocoon lot produced (1910) 17 white cocoons and 4 yellow cocoons; and another produced 14 white cocoons (both small sick lots).

In 1907 a Bagdad White female was mated with a Bagdad White male from 9 30 A M to 10 55 A M. and then with a French Yellow male from 10 55 A M to 12 15 P.M From this mating there were produced (1908) 25 white cocoons and 13 yellow cocoons Mating (1908) two of these white cocooners together produced (1909) a small lot divided equally between white cocoons and yellow cocoons (sick lot) Mating (1909) two of these white cocooners together produced (1910) a small lot of white cocooners containing one yellow cocoon (straggler?) (Wherever my records show a single yellow in an otherwise white lot or a single white in an otherwise yellow lot I prefer "straggling" to any other explanation!) A mating (1909) of two yellow cocooners produced (1910) a small yellow lot containing one white cocoon A mating (1908) of a white and a yellow from the 25 white, 13 yellow lot produced (1909) a small lot composed equally of white and of yellow cocooners. Mating (1909) two of these white cocooners together produced (1910) 23 white cocoons and 2 yellow cocoons.

In 1907 another Bagdad White female was mated with a Bagdad White male from 9 30 A M to 10.55 A M. and then with a French Yellow male from 10 55 A M to 12 15 P M From this mating there were produced (1908) 33 white cocoons and 19 yellow cocoons Mating (1908) two of the yellows produced (1909) a small lot equally divided between yellow and white cocoons Mating (1909) two of these white cocooners produced (1910) 9 white cocoons and one yellow Mating (1908) a yellow and a white from the half yellow, half white F_1 generation produced (1909) 22 white cocoons And mating (1909) two of these together produced (1910) a small lot of all white cocooners. Mating (1908) another yellow with another white from the F_1 generation produced (1909) 6 white cocoons and 10 yellow cocoons. Mating (1909) two of these yellow cocooners produced (1910) a small lot equally divided between yellow and white cocoons. Mating (1908) two white from the F_1 generation produced (1909) a small lot all white except for a single yellow cocoon And mating (1909) two of these whites together produced (1910) an all white lot of cocoons

In 1907 a French yellow female was mated with a French yellow male from 9.15 A.M. to 10 45 P M and then with a Bagdad white male from 10 45 A M to 12·15 P M From this mating there were produced 57 white cocoons and 74 yellow cocoons Mating (1908) two yellows of this F_1 generation produced (1909) 22 yellow and 8 white cocoons Another similar mating (1908) produced (1909) 23 yellow and 2 white cocoons And still another produced 14 yellow and 5 white cocoons. Mating (1908) a yellow and a white of the F_1 generations produced (1909) 17 yellow and 19 white cocoons Another similar mating (1908) produced (1909) 21 yellow and 17 white cocoons Mating (1909) two whites of the F_2 generation produced by two yellow parents produced (1910) an all white lot Mating (1909) two more whites of this F_2 lot produced (1910) another all white F_3 lot Mating (1909) two yellows from this same F_2 lot produced (1910) an all yellow lot Mating (1909) another pair of these F_2 yellows produced (1910) 20 yellow and 9 white cocoons Mating (1909) two whites of the F_2 generation produced by a white × yellow produced (1910) 25 whites, 11 yellows and a double cocoon spun together by a white cocooning larva and a yellow cocooning larva Another mating (1909) of two whites from this same F_2 lot produced (1910) 19 white cocoons and 6 yellow cocoons.

In 1907 a French Yellow female was mated with a Bagdad White male from 9 40 A.M to 11 10 A M and then with a French Yellow male from 11 10 A M on to the death of the moths This mating produced (1908) 14 white cocoons and 140 yellow cocoons. Mating (1908) two of the white cocooners produced (1909) 30 white cocoons and 10 yellow cocoons Mating (1909) two of these F_2 generation white cocooners produced (1910) 69 white cocoons and no yellows. Mating (1908) two more of the F_1 generation white cocooners produced (1909) 20 white cocoons and 10 yellow cocoons. Mating (1909) two of the F_2

generation white cocooners produced (1910) a small sick lot, partly white and partly yellow Mating (1909) two of the F_2 generation yellow cocooners produced (1910) a small weak lot of 12 yellow cocoons and 2 white cocoons Mating (1908) two of the F_1 generation yellow cocooners produced (1909) 18 yellow cocoons and 2 white cocoons Mating (1909) two of the F_2 yellow cocooners produced 4 yellow cocoons and one white cocoon Mating (1908) two more of the F_1 generation yellow cocooners produced (1909) 59 yellow cocoons and no white cocoons Mating (1909) two of these F_2 yellow cocooners produced (1910) 47 yellow cocoons and no white cocoons Mating (1908) a yellow cocooner and a white cocooner of the same F_1 generation lot produced (1909) 18 white cocoons and 14 yellow cocoons Mating (1909) two of these F_2 white cocooners together produced (1910) 29 white cocoons and 11 yellow cocoons Mating (1909) two of the yellow cocooners of the F_2 lot produced (1910) a sick lot of 3 white cocoons and 1 yellow cocoon Mating (1908) another yellow and white pair of the same F_1 lot produced (1909) 10 white cocoons and 10 yellow cocoons Mating (1909) two of these white cocooners produced (1910) 93 white cocoons and 25 yellow cocoons Mating (1909) two of the F_2 yellow cocooners produced (1910) 8 white cocoons and 35 yellow cocoons

In 1907 a French Yellow female was mated with a Bagdad White male from 9 40 A M to 11 10 A M and then with a French Yellow male from 11 10 A M to 12 25 P M This mating produced 56 salmon (i e, pinkish yellow) cocoons and 34 salmon to golden yellow cocoons (All of these in the general category yellow but varying in shade from pinkish yellow to deep old gold yellow) Mating (1908) two salmon cocooners produced (1910) 13 salmon cocoons and 3 white cocoons Mating (1909) two of these F_2 salmon cocooners produced (1910) all salmon lot. Mating (1908) another salmon F_1 pair produced (1909) 17 salmon cocoons and 8 white cocoons. Mating (1909) two of these F_2 salmon cocooners produced (1910) 10 salmon cocoons and 6 white cocoons.

So much for double matings between Bagdad Whites and French Yellows Now for a series between Bagdad Whites and Istrian Yellows.

In 1907 an Istrian Yellow female was mated from 9 A M to 10 30 A M with an Istrian Yellow male and then from 10 30 until 12 with a Bagdad White male This mating produced (1908) 55 yellow cocoons and one (straggler?) white cocoon Mating (1908) two of the yellow cocooners produced (1909) 10 white cocoons and 23 yellow cocoons Mating (1909) two of these yellow cocooners produced (1910) 2 white cocoons and 12 yellow cocoons Mating (1908) another pair of yellow cocooners of the same F_1 lot produced (1909) 13 white cocoons and 28 yellow cocoons Mating (1908) still another yellow pair from the same F_1 lot produced (1909) 10 white cocoons and 24 yellow cocoons Mating (1909) two of these white cocooners produced (1910) 4 white cocoons and no yellows Mating (1909) two yellow cocooners of the same F_2 lot produced 16 white cocoons and no yellow cocoons

In 1908 an Istrian Yellow female was mated with a Bagdad White male from 10 30 A M to 12 M and then with an Istrian Yellow male from 12 to 1 30 P M This mating produced 30 yellow cocoons Mating (1909) two of these yellows produced (1910) 16 yellow cocoons and 4 white cocoons Mating (1909) another pair of the F_1 yellows produced 19 yellow cocoons and 4 white cocoons

In 1907 a Bagdad White female was mated with a Bagdad White male from 9 45 A.M to 11 A M and then with an Istrian Yellow male from 11 A M. to 12·15 P M This mating produced (1908) 15 white cocoons and 57 yellow cocoons Mating (1908) two of these white cocooners together produced (1909) 11 white cocoons and no yellows. Two other pairs of white cocooners from the same F_1 lot produced (1909) small all white lots. From each of these three all white F_2 lots was mated (1909) one pair, and each mating produced (1910) a very small weak all white lot Mating (1908) two yellow cocooners from the original F_1 generation lot produced (1909) 22 yellow cocoons and 6 white cocoons. Mating

(1909) two of these white cocooners produced (1910) 35 white cocoons and no yellows Mating (1909) two yellow cocooners produced 24 yellow cocoons and no whites Mating (1908) another pair of F_1 yellow cocooners produced (1909) 9 white cocoons and 20 yellow cocoons Mating (1909) two of these white cocooners together produced 25 white cocoons and no yellows. Mating (1909) two of the yellows together produced (1910) 12 white cocoons and 21 yellow cocoons Mating (1908) another pair of yellow cocooners from the original F_1 lot produced (1909) 4 white cocoons and 17 yellow cocoons Mating (1909) two of these yellow cocooners together produced 8 white cocoons and 20 yellow cocoons Mating (1908) a yellow cocooner and white cocooner of the original F_1 lot produced (1909) 12 white cocoons and 12 yellow cocoons Mating (1909) two of these white cocooners produced 19 white cocoons and no yellows Mating (1909) two of the yellow cocooners produced (1910) 10 white cocoons and 17 yellow cocoons Mating (1908) another yellow and white pair produced (1909) 16 white cocoons and 20 yellow cocoons Mating (1909) two of these white cocooners produced (1910) 6 white cocoons and no yellows Mating (1909) two yellows produced (1910) 8 white cocoons and 6 yellow cocoons Mating (1909) a yellow and a white produced (1910) 4 white cocoons and 12 yellow cocoons Mating (1908) another yellow and white pair produced (1909) 5 white cocoons and 31 yellow cocoons Mating (1909) two of these whites produced 19 white cocoons and no yellows Mating (1909) two of the yellows produced 9 yellow cocoons and no white cocoons

In 1907 a Bagdad White female was mated with an Istrian Yellow male from 9 45 A.M to 11 A M and then with a Bagdad White male from 11 A M to 12 15 P M This mating produced 41 white cocoons, many of them creamy white instead of the pure or faintly greenish-white characteristic of the Bagdad white race Mating (1908) two of these white cocooners produced (1909) 59 white cocoons And mating (1909) two of these F_2 white cocooners produced (1910) a small all white lot Similar F_2 and F_3 all white lots were obtained from another F_1 mating Mating (1908) another pair of F_1 white cocooners produced (1909) 46 white cocoons and 15 yellow cocoons Mating (1909) two of these white cocooners produced (1910) a small all white lot Mating (1909) two of these F_2 yellow cocooners produced (1910) an all yellow lot

In 1907 a Bagdad White female was mated with an Istrian Yellow male from 9 45 A M to 11 A M and then with a Bagdad White male from 11 A M to 12 15 P M (This was an exact duplicate of the 1907 double mating just described) This mating produced (1908) 48 white cocoons and 20 yellow cocoons Mating (1908) two of these white cocooners produced (1909) a small all white lot, and a mating (1909) of two from this lot produced (1910) a smaller all white lot Mating (1908) another white pair from the F_1 generation produced an all white lot, and a mating (1909) of two from this lot produced (1910) a small all white F_3 lot Mating (1908) two yellow cocooners of the F_1 lot produced 9 white cocoons and 12 yellow cocoons Mating (1909) two of these F_2 white cocooners produced a small all white lot, while mating (1909) two of the yellow cocooners produced (1910) a very small all yellow lot Another mating (1908) of two yellow cocooners of the original F_1 lot produced 26 yellow cocoons and one white cocoon and mating (1909) two of these F_2 yellow cocooners produced (1910) 14 yellow cocoons and 2 white cocoons Another mating (1908) of two yellow cocooners from the original F_1 lot produced 28 yellow cocoons and 12 white cocoons Mating (1909) two of these F_2 yellow cocooners produced 50 yellow cocoons and no white ones, while mating (1909) two of the white cocooners produced (1910) 15 white cocoons and 1 yellow cocoon (straggler?). Mating (1908) a yellow and a white from the original F_1 lot produced (1910) 40 white cocoons and 16 yellow cocoons Mating (1909) two of these white cocooners produced (1910) 28 white cocoons and 29 yellow cocoons, while mating (1909) two of the F_2 yellow cocooners produced (1910) 5 white cocoons

and 34 yellow cocoons. Another mating (1908) of a yellow cocooner and a white cocooner from the original F_1 lot produced (1909) 20 white cocoons and 19 yellow cocoons. Mating (1909) two of these white cocooners produced (1910) 70 white cocoons and no yellow ones, while mating (1909) two of these F_2 yellow cocoons produced (1910) 6 white cocoons and 9 yellow cocoons.

In 1907 a Bagdad White female was mated with a male Istrian yellow from 9.40 A.M. to 10.45 A.M. and then with a male Bagdad White till death of the moths. This mating produced (1908) 29 yellow cocoons. Mating (1908) two of these yellow cocooners produced (1909) 25 yellow cocoons and 8 white cocoons. Mating (1909) two of these F_2 whites produced (1910) a small all white lot. Mating (1908) another pair of the F_1 yellow cocooners produced (1909) 6 white cocoons and 12 yellow cocoons. Mating (1909) two of these F_2 white cocooners produced (1910) an all white lot. Mating (1909) two of the yellow cocoons produced 9 yellow cocoons and 6 white cocoons. Mating (1908) another pair of the F_1 yellow cocooners produced (1910) 30 yellow cocoons and 9 white cocoons. Mating (1909) two of these yellow cocooners produced (1910) an all yellow lot. Mating (1908) still another pair of the F_1 yellow cocooners produced (1909) 19 yellow cocoons and 4 white cocoons. Mating (1909) two of these F_2 yellow cocooners produced (1910) 29 yellow cocoons and 5 white cocoons.

These are the records. Their interpretation may be made by any one interested. In scrutinizing them for significance this should be remembered. In ordinary (single) matings of Bagdad White with Bagdad White only white cocoons are produced in F_1 and all following generations. In mating French Yellow with French Yellow or Istrian Yellow with Istrian Yellow only yellow cocoons are produced in F_1 and all following generations. In mating Bagdad White with Istrian Yellow usually all the cocoons of the F_1 generation are yellow. Mating these together usually produces in F_2 generations 3 yellow to 1 white, the Mendelian behavior. In mating Bagdad White with French Yellow the dominance of yellow is not so steadfast. There is, as I have shown and particularly emphasized in my 1908 paper, more or less aberration from the Mendelian rules in this mating. And indeed, these aberrations are likely to occur in any other crossing of silkworm races. The usual inheritance behavior of silkworm cocoon characters is, however, Mendelian. The aberrations constitute what I have called "strain and individual idiosyncrasies." This simply means that I believe that there is more in the order of inheritance than is covered by Mendelism. The Mendelian elements in this order are becoming recognizable and familiar. The other elements are not yet so obvious to us.

In these double matings the aberrations are abundant and conspicuous. After a double mating the whites of the F_1 generation mated with other whites of the same generation do not always produce whites. They may produce both yellows and whites. Or this latent carrying of the yellow character by these presumably strictly recessive (white) carriers may not be manifest till an F_3 generation. What does this mean?

In seeking an answer, the state of affairs as regards actual fertilization in these double mating cases must be kept in mind.

The female receives during an hour's or two hours' coupling a large number of fertilizing cells from a male of her own race (and hence her own cocoon characters). She then receives during another hour's or two hours' coupling a presumably equal number of germ cells from another male of different race (and different cocoon characters). These two lots of active spermatozoa are held in the spermatheca. Is one group above or in front of the other, so that when an egg arrives opposite the opening of the spermatheca it will necessarily be fertilized by one of this upper or front group (the group provided by the second male)? Or do the actively motile spermatozoa become thoroughly mingled in their fluid vehicle so that access to the egg will be according to the law of probabilities? More likely the latter alternative should prevail.

When, however, a spermatozoan enters the egg through the micropyle this micropyle should, by analogy with the observed conditions in various other insect eggs, become closed, thus preventing poly-fertilization If this is so then a double mating should after all result in but a single fertilization, and these fertilizations should be roughly divided between the two male types

Thus in double mating a female Bagdad White with Bagdad White and Istrian Yellow males, the fertilizations should be, roughly, equally divided between pure race Bagdad White and crossed Bagdad and Istrian Yellow And in accordance with these fertilizations half of the F_1 generations thus produced should be white cocooning and half yellow cocooning (yellow being dominant in crossings with white) If an Istrian Yellow female is mated with both Istrian Yellow and Bagdad White males F_1 generations should always be composed of all yellow cocooning individuals Or if in these double matings all of the fertilizations are effected by spermatozoa of one of the males only then the F_1 lots should be either all white cocooning or all yellow cocooning F_2 generations from these lots should follow the Mendelian order and break when the F_1 individuals are hybrids and not break when they are pure race progeny

But the data given above do not reveal the expected behavior They evidence a considerable perturbation in the order of inheritance The F_1 lots are not always all white or all yellow, or equally divided between white and yellow as they seemingly should be Or if such all white or all yellow F_1 lots are produced, they often throw both yellows and whites in F_2 lots when only yellows or only whites should have appeared. Or if they do produce all white or all yellow F_2 lots intermating in these lots may produce both yellows and whites in F_3 lots. In a word the inheritance behavior is not that which it should be in animals usually following a Mendelian order, if the only influence at work on the egg is the nuclear content of a single pure race spermatozoan.

What, then, is causing this pertubation in the order of inheritance? Do the eggs in double-mated females receive more than one spermatozoan and are these spermatozoa often the representatives of both the races used in the double mating? Or can the egg be in any way influenced by the mere presence in the spermatheca of spermatozoa representing both of a pair of allelomorphic heritable characters? Can fluids carrying the spermatozoa have any influence during fertilization? Can the spermatozoa of one type influence those of the other type during their enforced companionship for several hours or days in the female spermatheca?

All that we think we know of the mechanism of fertilization and heredity makes us answer "No" to each of these questions Then why should the order of inheritance in the silkworm moth be different in the generations after these double matings from the order in the generations following a single mating?

"Biographical Memoir of Joseph Leidy," Henry Fairfield Osborn

THE AMERICAN MATHEMATICAL SOCIETY

THE one hundred and fifty third regular meeting of the society was held at the University of Chicago on Friday and Saturday, April 28–29, 1911, the occasion being especially marked by the presidential address of Professor Maxime Bôcher on "Charles Sturm's Published and Unpublished Work on Differential and Algebraic Equations" This was the first regular meeting of the society, except the summer meetings, that has been held elsewhere than in New York city The attendance exceeded all previous records, reaching a total of 115, including 88 members. Fifty three papers were presented at the four sessions

The president of the society, Dean H B Fine, of Princeton University, occupied the chair, being relieved by Professor G A Miller and Vice president G A Bliss The council announced the election of the following persons to membership in the society Professor H Bateman, Bryn Mawr College, Mr Samuel Beatty, University of Toronto, Professor J H Griffith, University of Michigan, Mr E J Moulton, Harvard University, Mr George Spitzer, Agricultural Experiment Station, Purdue University, Professor C J West, Ohio State University Eleven applications for membership in the society were received

Professor L E Dickson was reelected to the editorial board of the *Transactions* for a term of three years A committee was appointed to arrange for the summer meeting and colloquium to be held at the University of Wisconsin in 1913

Friday evening was devoted to the usual dinner, at which 73 members were present

The following papers were read at this meeting

Daniel Buchanan "A class of periodic solutions of the problem of three bodies, two of equal mass, the third moving in a straight line"

H E Buchanan "An expansion of elliptic functions with applications"

D R Curtiss "Relations between the Gramian, the Wronskian, and a third determinant connected with the problem of linear dependence"

L L Dines "On the representation of resultants of polynomials in one variable"

L L Dines· "On the solution of three equations for three variables in terms of others"

W D MacMillan "A reduction of a system of power series to an equivalent system of polynomials"

W D MacMillan· "A method for finding the solutions of a set of analytic functions in the neighborhood of a branch point"

R L Moore "On the transformation of double integrals"

Maxime Bôcher (presidential address) "Charles Sturm's published and unpublished work on differential and algebraic equations"

L P Eisenhart· "A fundamental parametric representation of space curves"

A E Young "On certain orthogonal systems of lines and the problem of determining surfaces referred to them"

Arnold Emch "The differential equation of curves of normal stresses in a plane field."

A B Frizell. "A set of postulates for well ordered types"

C J Keyser· "Sensuous representation of paths that lead from the inside to the outside of

an ordinary sphere in point four space without penetrating the surface of the sphere"

Edward Kasner "The subdivision of curvilinear angles"

R D Carmichael "The general theory of linear q difference equations"

R D Carmichael "Note on multiply perfect numbers"

G A Miller "Isomorphisms of a group whose order is a power of a prime"

R. G D Richardson "Theorems of oscillation for two self adjoint linear differential equations of the second order with two parameters (second paper)"

J B Shaw. "Quaternion functions of three parameters"

J E Rowe "The combinants of two binary cubics and their geometrical interpretation on the rational cubic curve"

U G Mitchell "Geometry and collineation groups of the finite projective plane $PG(2, 2^3)$"

G E Wahlin "The decomposition of rational primes into ideal prime factors in the field $k(\sqrt[p]{m})$"

L C Karpinski "An Italian Algebra of the fifteenth century"

C H Sisam "On hyperconical connexes in a space of r dimensions"

R E Root. "Iterated limits of functions on an abstract range"

E B Van Vleck "On the generalization of a theorem of Poincaré"

E B Van Vleck "On the classification of collineations"

A R Schweitzer "On the philosophy of Grassmann's extensive algebra"

A R Schweitzer "On the 'working hypothesis' in the logic of mathematics"

W B Ford "A set of sufficient conditions that a function may have an asymptotic representation in a given region"

W J Montgomery "The classification of twisted curves of the fifth order"

William Marshall· "On Hill's differential equation in the theory of perturbations"

H Bateman "The fundamental equations of the theory of electrons and the infinitesimal transformation of an electromagnetic field into itself"

N J Lennes "Curves and surfaces in analysis situs"

N J Lennes· "Extension and application of a theorem of Ascoli."

L I Neikirk. "Substitution groups of an infinite degree and their related functions"

James Maclay: "Parabolic curves"

J. A Nyberg· "Projective differential geometry of rational cubic curves"

E B Stouffer. "Invariants of linear differential equations with applications to ruled surfaces in five dimensional space"

W D MacMillan "A general existence theorem for periodic solutions of differential equations of a certain type"

A R. Crathorne "The catenary with variable end points"

F R Moulton "Periodic orbits of superior planets"

F R Moulton "On the curves defined by certain differential equations"

F H Safford "An identical transformation of the elliptic element in the Weierstrass form"

W H Roever "Southerly deviation of falling bodies (third paper)"

C N Moore "Convergence factors in double series"

L E Dickson "On the negative discriminants for which there is a single class of positive primitive binary quadratic forms"

L E Dickson "On Fermat's 'descente infinie'"

L E Dickson "On perfect numbers and Bernoullian numbers"

O E Glenn "On expressing a quantic in terms of assigned powers of a given quantic"

G R Clements "Implicit functions defined in the neighborhood of a point where the Jacobian determinant is zero"

R W Marriott "Determination of the groups of isomorphisms of the groups of order p^4"

The summer meeting of the society will be held at Vassar College on Tuesday and Wednesday, September 12-13

THE AMERICAN PHILOSOPHICAL SOCIETY

AT the stated meeting of the society on April 7, Rear Admiral G W Melville (U S Navy, retired) read a paper on "A Century of Steam Navigation"

The author said In looking back over the history of the human race we are struck with the fact that from time to time some genius brings to light, or develops a principle which forever after is a guide in our thinking Such was Lord Bacon's exposition of inductive logic, which has been the basis of all scientific advancement

Basing his argument on the above theory, the admiral followed the growth of steam navigation from the time of the inventions of James Watt, down to the time of Fulton's first commercial steamer *Clermont*, down to the time of the *Lusitania* and *Mauretania* of to day

He spoke of the varied improvements from that time up to the present time, including the many improvements, not only in ships and ship building from the wooden hulls to the present steel hulls, but the engines and boilers through their various stages of improvements, commencing with a low steam pressure of 10 pounds to the square inch up to the present time of about 300 pounds pressure per square inch

He traced through the various steps the great evolution of steam ships from those of about 500 tons to those of 40,000 tons Of necessity in a short lecture of but 40 or 45 minutes, a very

rapid tracing of the growth of steam navigation and marine engineering had to be quite limited. Nevertheless, the lecture seemed to be of great interest to his audience. And the fact of the growth of steam ships from the paddle wheels used to a large extent in the forties of the last century, through the propeller systems, and finally of the great advances made through the steam turbine, which is only an improvement of Heroes's steam turbine of 2,000 years ago.

He mentioned the famous steamer *Great Eastern*, which was a wonder in her day, which is nearly a half century ago. She was simply about fifty years in advance of her time, for although a great engineering success, she was not a commercial success, which is the real measure in these days of what is considered a success in commercial life.

He laid great stress on the improved material with which the engineer could work to day, without which it would be impossible to build the great vessels of 30,000 tons displacement, and 70,000 horsepower.

Another fact which he pointed out, and which is worth noting, was that high speeds properly belong to big ships, because experiments had shown that for a higher speed the resistance of a large ship per ton of displacement was very much less than that of a small one.

He dwelt upon the different types of battle ships, from the *Dreadnought* type down to the small torpedo boat and torpedo-boat destroyer, stating that in naval construction it was necessary to have the various classes of ships to fill their particular positions in the battle fleet, the same as the different arms of the service in the army, such as artillery, cavalry, infantry, etc.

After the lecture illustrations were made of the lecture proper, by means of a series of illuminated lantern slides.

THE PHILOSOPHICAL SOCIETY OF WASHINGTON

THE 694th meeting was held on April 22, 1911, Vice-president Fischer in the chair. The following paper was read:

The Scientific Aspects of the President's Inquiry into Economy and Efficiency: DR. F. A. CLEVELAND, chairman, Committee on Economy and Efficiency.

The work that the committee had been asked to do was mentioned, and which, briefly stated, is that it was to make such concrete recommendations to the president as would enable him to act with greater economy and efficiency in the management of the business affairs of the government.

At the beginning there was little of scientific information of how the large business concerns of the government are organized or what the government is doing. The committee felt a grave responsibility. It assumed in the start that for progress and commendable results it was necessary to focus the attention of all in the service upon the subject of administration. This required a working hypothesis or common plan of cooperative effort or coordination. As the whole of this inquiry looks to something constructive, it first had to be decided what sort of information is needed by the man who is responsible for the conduct of the government's business.

The first work was to find out how the government is organized and what it is doing. The president asked each head of department to cooperate with the White House, and under their supervision the inquiries have been conducted. Diagrams and charts were exhibited showing the departmental organizations in their different divisions and branches and their activities, and how they are connected up and coordinated, these being based upon the reports and outlines of organization prepared by the several departments.

In describing the organization of the government's work, the speaker remarked in passing that one is really amazed when he knows what wonderful organizations some of the government offices are.

Reports were also secured describing the legal powers of the various departments and divisions of the government service throughout the country in order to ascertain the authority for the various activities pursued, and in these matters also the committee had appealed for their information to the men in the service who had been living the parts, to those directly concerned.

The committee assumed that the cost of the government's activities should be known, and that all should know that the administration of the government's affairs is economical. To ascertain this it is necessary to know, (1) that a thing is bought, (2) what is bought and (3) is it suitable for the purpose for which it is bought. Also in studying economy the relation of cost to results must be known.

The analysis of the costs of the government's activities in terms of administration, operation and maintenance were discussed, and how the analysis was applied in arriving at standards of judgment of costs in relation to results.

THE NEW HARVARD ENTRANCE REQUIREMENTS[1]

IN this address (a free abstract of which, written out later, is here given) it should be clearly borne in mind that the speaker is familiar only with eastern admission arrangements, and that what he says is wholly from the point of view of an eastern institution, with its own problems, in some respects different from those which meet the schools and universities of the west. Indeed, a knowledge of the real entrance requirements in any institution, as distinguished from the catalogue rules, can be gained only from an acquaintance with actual practise, for in the nature of the case the real requirements depend on the mode of administering the rules.

I

The earlier entrance requirements at Harvard, as at all contemporary institutions, were determined by the fact that the subjects studied in school were generally to be continued in college. It was accordingly necessary to know whether a boy who applied for admission had reached the point in Latin, Greek and mathematics where he would be able to go on with college work in those subjects. This was substantially the case until soon after the beginning of the administration of President Eliot in 1869. A process of radical modification in the Harvard entrance requirements then began, and at successive periods since, about ten years apart, there have been important and far-reaching changes.

[1] Address at the annual meeting of the Michigan Schoolmasters' Association, Ann Arbor, Mich., March 31, 1911.

The chief points in these changes appear to have been three · (1) a substitute for Greek has been provided, (2) with the development of the elective system the subjects studied by college students have in most cases become different from those which they have pursued in their school courses, and it is consequently necessary to learn not the degree of their attainment in Latin, Greek and mathematics, but whether they are competent to carry on studies in history, economics, modern languages and science; (3) it has been intended to aid the schools by setting in the several examinations a standard for school work to which the schools can hold up their boys. In pursuance of this last idea there has been a tendency to provide examinations in some subjects in which hardly any boys were likely to offer themselves, but which some schools wished to teach, and in which the college was told that such an examination standard would be found valuable

In the successive changes made at Harvard, chiefly in 1871, 1878, 1886 and 1898, can be seen the working of these various motives, and especially can be traced a gradual process by which the substitute admitted for Greek, at first partial, has become complete, and has finally been made not much, if at all, more difficult than the Greek requirement

The present plan of Harvard entrance requirements was adopted by the faculty in 1898, although the form of statement has since become somewhat changed. It includes a large number of optional subjects, many of them having a weight of not more than one "point" in the system. These options are in some (and the most important) cases real, in the sense of being practically available for schools, but in most cases they are illusory, because very few of the schools from which boys come are equipped to fit boys in these less usual subjects The chief technical peculiarity of the Harvard system is that the numerical values attached to the different subjects are not based wholly on the relative time supposed to have been expended on those subjects in the high-school course, but have been adjusted on the theory that work done in the last two years of the high-school course ought to be given a higher rating than the work of younger boys Accordingly, in determining the "ratings" a coefficient was introduced corresponding to the stage in the school course at which the subject would commonly be studied.

II

Under this system of complete examinations for all high-school studies, which differs but little in theory from that of the other eastern institutions where examinations are required, some good results have been felt in the schools from the establishment in certain fields of study of definite standards tested by a college examination, and in general the system has provided a method, though an imperfect one, of selecting from the whole body of applicants those who were best fitted to undertake college work. About 75 per cent. of those applying have usually been admitted to the freshman class, as is shown in the table given below. At the same time certain bad results have been more and more clearly perceived, both from the point of view of the college and from the side of the schools The latter, indeed, have not been slow to present complaints And these bad results seem to be necessarily consequent upon the system itself. The gradual perfecting of an inherently defective type of machine has naturally brought out more and more clearly the working of its defects.

1 The system has resulted in loading a

large part of the freshman class, usually amounting to one half or more, with entrance conditions, and thereby making more difficult the task of the weaker members of every entering class From the college point of view this difficulty has become intolerable, since it prevents the establishment of a proper pace of work for freshmen

2 The Harvard system of examinations can ordinarily be prepared for without serious difficulty by any school which devotes itself mainly or largely to that end, and which boys attend for three or four years before entering college and with the purpose of fitting themselves for Harvard It is not, however, adjusted to the courses of many excellent schools throughout the country—schools wholly occupied with substantial academic subjects and doing first-rate work in those subjects, and it is likely to exclude any boy who makes up his mind late in his school course that he wishes to go to Harvard In other words, it is a system which was natural so long as resort to Harvard was wholly from private and endowed schools and a half dozen public high schools which made a business of fitting for Harvard and other eastern institutions. If Harvard is to offer the melting pot of a common academic life to boys from many parts of the country, it must adapt itself to the best systems of public education maintained in those widely distant regions. By dictating the whole school course as it does, the present Harvard entrance system unduly restricts the possibility of resort to Harvard College from other schools than that very small number which have for one of their primary objects to be Harvard fitting schools

3. As a method of selecting the best from the whole body of applicants for admission to the freshman class, the present system is imperfect It admits to the class a certain number of boys who can do nothing well, but have been crammed to pass every one of the examinations with the lowest pass mark These boys often get in clear of conditions, but usually come to grief in the first semester. A satisfactory system would exclude them from admission On the other hand, some have to be rejected who would do well in college if they once got in

Harvard College does not crave any considerable increase in numbers What it does desire is the resort of about the same number of young men, but of better students from a wider range of territory We should like, not a larger number of freshmen, but a larger number of applicants from whom we could make our selection of the best

As the three evil results already mentioned are observed from the side of the college, so the two following have been urged, and it is believed with justice, by the schools

4 A system of examinations which, like the present one, aims to test every subject studied in a four-year school course makes it necessary for every subject to be continued in the course in some form until the time for the examinations Under the system of the German gymnasium the subjects are practically all carried down to the close of the last year, the stream of the minor subjects being kept slender yet sufficient to maintain the flow. The American school system is of a different character, and consequently it is necessary for the American school to review in the last year, or the last two years, those subjects upon which the boy is presently to be examined. This produces a spirit of "cram," deeply regretted by the school-masters, together with a serious overcrowding of the last year, or two years, of the school course.

An elaborate examination of school programs from good schools in different parts of the country recently made at Harvard has fully convinced us that the complaints of the schoolmasters in this matter are justified. If it be urged that the examinations can now be spread over three years, it is to be observed that the college examinations are necessarily adapted to the stage of maturity of boys nearly ready to enter college, and are, consequently, for the most part out of the range of a boy completing the second year of his high-school course

5 Under the present system of entrance to Harvard College, not only is the course of study in the schools fixed from above, but also the methods of teaching have been dictated by the college This has taken from the schools freedom to experiment with their own methods of education, a freedom which able and enterprising teachers crave, and ought to have A certain relief, it must be said, has been found here in the examinations of the College Examination Board, but it appears to be only a partial one

6 One further bad result upon the schools more directly under the influence of Harvard should be mentioned The examination system has enfeebled their power to take responsibility for the quality of their own product As Harvard has undertaken to test every subject studied in the school course, the school has been responsible for meeting these tests, not for maintaining its own ideal and type of education Indeed, it was hardly open to it to form its own educational ideal or specific type at all

III

These various incidental bad results of the present system have led the Harvard faculty to a complete reconsideration of the principles which ought to govern a plan of entrance requirements, and to the adoption of a new system which, for the present, will be maintained side by side with the old system, the applicant having his choice whether he will come up for admission under one or the other plan

In framing the new system the consideration chiefly in mind has been that entrance requirements must always test two things

1. Whether the applicant has had an adequate school course Inasmuch as a bachelor's degree represents the completion of the whole course of liberal education, it necessarily includes a guarantee that the earlier as well as the later part of the student's education has been adequate in range and intensity. The college is responsible not merely for college work, but also for knowing whether the school work has been devoted to such subjects as, in its opinion, may properly form a part of the education finally attested by the bachelor's degree

2 What result has been accomplished by such a course of school study in developing effective ability in the individual boy or girl This latter test has for its object to determine whether the applicant is likely to be able to do college work well.

Now these two ends for which college entrance requirements exist are entirely different in nature. The character of the applicant's course of study is a very different thing from the practical result in the boy as he stands. The former can be adequately ascertained by proper inquiry and by inspection of the school course he has actually pursued; the latter can only be determined by recitations, examinations, or some similar test, conducted either by the school or the college. The present examination system undertakes to reach both these ends by one instrument—a system of

examinations The results have been outlined It would seem better to adopt for each of these ends a method directly contrived to accomplish that particular purpose, and not to try to perform two distinct processes by a machine mainly adapted to one only

Both in regard to the course of study and to the result of that study, the school and the college have each a distinct responsibility The general type of school course which is to be accepted as a part of the whole education to be attested by the degree of A B or S B, may, and indeed must, be determined by the college which gives the degree But under that general type the details of curriculum and of methods of instruction are more likely to be effectively arranged by the school itself than by the authorities of the college To deprive the school of its freedom and consequent responsibility is to weaken its power of maintaining and pursuing an educational ideal On the other hand, the testing of the result of the school education belongs to the college, and an adequate test ought to give evidence of general intellectual power, not merely of the faithfulness with which a boy has studied individual subjects at school The idea that an education consists in absolving individual courses, whether at school or college, is, at the present day, the root of much evil

In New England, as elsewhere, one of the difficulties of which the schools have complained has been alleviated by the certificate system, which, through the coöperation of the colleges in the New England Certificating Board is now well organized with strict standards Colleges which thus give to certain schools the privilege of certifying to the preparedness of their graduates for college thereby relax their control, not indeed over the subjects studied, but over the method of instruction in the individual subjects, and this has proved a considerable relief But the certificate system, at least as organized in New England, violates both of the principles which have been laid down above Under it the domination of the college over the topics which are to make up the school curriculum, over the relative weight which shall be given them, and over other details which properly belong to the judgment of the school, is quite as close and harassing as under the examination system On the other hand, that portion of the task which is the rightful prerogative of the college, namely, the determination of how well the schools have done their work, is abandoned by the college and handed over to the headmasters of the schools, who certify, not merely that the boy has done such and such work in his school course, but that, in the opinion of the master, he is fit to enter college. In both these matters the certificate system has reversed the proper procedure, and puts the responsibility on the wrong side

IV

Under the influence of considerations like these, the new plan already spoken of has been adopted at Harvard College The following statement of it has been sent out widely

NEW REQUIREMENTS FOR ADMISSION TO HARVARD COLLEGE

To be admitted to Harvard College, a candidate

(1) Must present evidence of an approved school course satisfactorily completed, and

(2) Must show in four examinations as explained below that his scholarship is of a satisfactory quality:

SCHOOL RECORD

A candidate must present to the committee on admission evidence of his secondary school work in the form of an official detailed statement showing

(a) The subjects studied by him and the ground covered.
(b) The amount of time devoted to each.
(c) The quality of his work in each subject.

To be approved, this statement must show:
(a) That the candidate's secondary school course has extended over four years.
(b) That his course has been concerned chiefly with languages, science, mathematics and history, no one of which has been omitted.
(c) That two of the studies of his school program have been pursued beyond their elementary stages, i. e., to the stage required by the present advanced examinations of Harvard College or the equivalent examinations of the College Entrance Examination Board.

THE EXAMINATIONS

If the official detailed statement presented by the candidate shows that he has satisfactorily completed an approved secondary school course, he may present himself for examinations in four subjects as follows:
(a) English.
(b) Latin, *or*, for candidates for the degree of S.B., French or German.
(c) Mathematics, or physics, or chemistry.
(d) Any subject (not already selected under (b) or (c)) from the following list:

Greek	History	Physics
French	Mathematics	Chemistry
German		

These four examinations must be taken at one time, either in June or in September.

In announcing this plan, the committee on admission wish to point out that it differs in essential principles from the old plan now in use, and that therefore comparisons between the new requirements and the old will be misleading if any attempt is made to express the new requirements in the terms of the old. Under this new plan the college does not intend to prescribe in detail the school course of the boy who wishes to enter, either directly by naming and defining subjects, or indirectly by an elaborate system of rating the studies of a school course in points or units. On the contrary, the college accepts the judgment of a school as to a candidate's program, subject only to the general limitations stated above. It is not necessary, therefore, for a school to fit a candidate's course to detailed definitions of subjects. A good student who has had a rationally planned course in a good school should have no difficulty in proving his fitness for admission, even though his decision to come to Harvard be made late in his last school year. Under the new plan every school maintaining the kind of course indicated will be free to work out its own system of education in its own way. The college, on its part, undertakes only to test the intellectual efficiency of the boy at the time of his graduation from school. For this reason the examinations can not be divided.

A second important difference between the new requirements and the old is the emphasis put in the college examinations upon quality of work. The new plan contemplates examinations different from those now used with respect both to their character and the method in which they will be administered. It is hoped to secure a type of examination which shall be adapted to various methods of teaching, and which shall contain questions sufficient in number and character to permit each student to reveal the full amount and quality of his attainment. In administering examinations under this plan, the committee will always consider examinations in connection with school records, and will endeavor to see not whether a candidate has done a certain prescribed amount of work in a certain way, but whether the general quality of the candidate's scholarship is satisfactory. If a candidate is admitted, he will be admitted without conditions; if he is refused admission, no credit will be given for examinations in the separate subjects in which he may show proficiency, and the refusal will mean that his school record and his college tests do not show that he has the scholarship which makes his admission to Harvard College desirable.

The admission of a candidate under this plan, therefore, depends upon good scholarship as shown in two ways—in his school work and in his college tests. He can not secure admission by scoring points or by working up examinations one or two at a time. He must have done good work in his school according to the testimony of his teachers, and he must meet successfully college tests at the time when he is ready to enter.

In introducing this plan, which departs considerably from schemes of admission now in general use, the college is already aware of various grave difficulties. It will doubtless be difficult to prepare a type of examination paper sufficiently flexible to fit various methods of instruction in various parts of the country, and to enable all candidates to exhibit the full amount and quality of their attainments. To accomplish this end, the committee on admission are authorized to advise

with school teachers in regard to the preparation of papers and the methods and standards of marking, and they confidently hope for the cooperation of schools in working out a plan which they believe will serve the common interests of both schools and colleges

The scheme, as above outlined, aims to determine by inquiry whether the boy's school work shall be counted as a sufficient preliminary education, and then to test by a sufficient number of examinations, not however, covering the whole school course, what has been the result of the education in the boy's power to do intellectual work. Each of these methods seems apt to the end desired, and careful provision has been made for keeping these two inquiries distinct

The essence of the scheme is, in fact, that the admission of boys to college is now entrusted to a committee which is expected to use a large discretion under the limits laid down in the regulations. This committee will assemble a sufficient general knowledge of the schools from which boys come, such knowledge as can now be obtained by various trustworthy methods, even from distant parts of the country. It is further provided, through the certified record of the boy presented by the master of the school and through the results of the examinations, that adequate information on the two points emphasized above will be at the committee's disposal

The restriction upon the type of school which will be allowed to send boys up to become candidates for the bachelor's degree is here made, not, as at present, through the list of examination subjects with their accurate ratings, but through the statement of the course actually pursued by each boy, with the grades attained. The college does not intend to alter at all its policy of requiring that the boy's education shall have consisted mainly of substantial academic subjects. No school course will be accepted which includes any large dilution of manual and technical work

The examinations are to be of a somewhat different type from those hitherto used, or, at any rate, the treatment of the examinations by the readers and by the committee is intended to be different from that which has been given to examinations in the past. The purpose of the examinations is not to test the work of the several courses of the school, but to sample the boy, as a cargo of cotton might be sampled from taking tests from different representative bales. Further, the object of the examination is not to see whether the boy can get a pass-mark in any one, or in all, of the subjects. It will rather be to bring out how much the boy knows. It is hoped that for his free (fourth) subject he will choose the field he can do best in, and so will be given a chance to exhibit himself at his best. Likewise, it is hoped that the schools will now be able to carry boys to more advanced work in those subjects (as, for example, classics or mathematics) in which they are best equipped—for they can do so with the confidence that the result of that special proficiency in certain subjects will be manifest in the examination, and recognized by the admission committee. The marking of the books under the new system will require that in every case a statement by the reader in words shall give his opinion of the actual quality of the boy as exhibited in that examination. There will be no mechanical adding of grades. It will be impossible to enter on a bare pass-mark in the several subjects. Indeed, it is difficult to say under the new system what would constitute "passing" any one examination. The only "passing" that is contemplated is the evidence, ***drawn from the four examinations taken together***, that the boy has at-

tained a satisfactory quality of mind He is expected to make a *creditable* exhibition of himself, and it is hoped that the system will exclude the boy who, under the old system, probably by the aid of a skilful tutor, can just scrape through every examination It is hoped that in good schools the new system will make it easier for the school-master to prepare boys for Harvard, but it is not intended to make entrance to college in any way easier for the *boys*

Inasmuch as the inquiry relates to the intellectual power of the boy at the moment when he stands ready for entrance, it is obvious that the examination can not be divided into preliminary and final For the same reason, the evil of conditions will be wholly eliminated by the new system A boy either is or is not fit to enter college If he is not fit, then he must either abandon the idea or else go back to school and study until he becomes ready There can be no conditions

It is not the intention by the new system either to raise or to lower the "standard" of admission. That is to say, it is hoped that in a four years' course the amount of intellectual effort which a boy has to put out in order to prepare for Harvard will be as before. But a smaller proportion of it will be mere cram.

Total number of applicants for admission to freshman class	808	798	688	770	786
Per cent admitted to freshman class ..	71.3	74.4	76.9	74.4	71.9

The present policy of Harvard in admitting students can be seen from the above statistics, which are complete for the years covered

Of those admitted in the past five years there are undoubtedly some who would have been rejected if they had been compelled to come up under the new system Many of these have failed, or will fail, to complete their college course, at least with credit Of those registered, some could probably have gained admission if the new system had been open to them, and of these a large proportion would very likely have shown distinction in their subsequent college course What the effect will be upon the size of the classes admitted to Harvard College, when most of the applicants shall come up under the new system, is not easy to forecast There has been some apprehension that the percentage of boys admitted will be considerably reduced, but it is hoped that the larger number of schools which will now find themselves able to prepare boys for Harvard will counterbalance this tendency, and prevent any large reduction in the numbers of the future entering classes

V

In conclusion, a few words may be added as to the general results which it is hoped to secure from this new plan when it goes into full operation These results are of widely varying kinds

1 Harvard College hopes to secure a better body of freshmen, for they will have been selected from the whole number of applicants by more nicely adapted methods, and they will be free from conditions and therefore able to do better work.

2. A large number of excellent schools of the accepted type, now unable in their regular curriculum to fit boys to enter Harvard College, will, it is hoped, under

the new system find themselves able to do so without extra work This applies to some public schools in New England and to a large number in other parts of the country At present, there are only fourteen public high schools which have sent to Harvard College one boy a year for the past ten years, and all of these are in eastern Massachusetts.

These two results are primarily significant for the college The other desired results, if they come about, are broader in their educational significance

3. Schools of the approved type will, so far as Harvard College is concerned in the matter, gain the freedom which they require for doing their best work, since the new system will make it possible for them to concentrate their efforts by treating more thoroughly fewer subjects, or fewer topics of a subject The great need of students in schools, as well as in colleges, is that they should acquire a habit of doing well what they undertake to do, the greatest evil in education at present is that students are satisfied with mediocrity

4 The new system gives some help toward an adjustment of the problem of educating together in one school students preparing for college and students preparing for other callings. It does not wholly solve this problem, but it ought to tend somewhat to relieve it The problem itself is insoluble. Preparation for a definite vocation must be determined by the character and needs of that particular vocation, and college is a vocation for a young man of seventeen to twenty-one just as much as service in a banking house or factory, and, like those vocations, it has its own conditions of fitness. Different needs can not all be provided for under one system of education. Nevertheless, some parts of a school course are an excellent preparation both for college and for an immediate practical career, and the new system of examinations, under which requirements in specific subjects are kept as high as before but the subjects less closely defined, will, it is hoped, give as much freedom here as the nature of the case permits.

5 The new plan leads away from emphasis on single courses, and insists on the significance of the education taken as a whole In accord with this underlying idea it is free from all attempts to determine the relative value of subjects as expressed in numerical ratings In this respect it has a general educational importance, and ought to remove many causes of friction now existing between schools and colleges

JAMES HARDY ROPES
HARVARD UNIVERSITY

THE BOLYAI PRIZE II

INTEGRAL EQUATIONS

In these latter years, Hilbert has above all occupied himself with perfecting the theory of integral equations We know that the foundations of this theory were laid some years ago by Fredholm, since then the fecundity of his method and the facility with which it may be applied to all the problems of mathematical physics approve themselves each day with more luster. This is certainly one of the most remarkable discoveries ever made in mathematics, and for itself alone it would merit the very highest recompense, if to-day, however, it is not to the first inventor, but to the author of important improvements, that we have decided to award the Bolyai prize, it is because we must take into consideration not only Hilbert's works on integral equations, but the totality of his achievement, which is of importance for the most diverse branches of mathematical science and of which the other parts of this report permit us to appreciate the interest

But we can not enter upon this subject without paying homage to the immense service which Fredholm has rendered to science.

The theory of Fredholm is a generalization of the elementary properties of linear equations and determinants. This generalization may be followed up in two different ways: on the one hand, by considering a *discrete* infinity of variables connected by an infinity of linear equations, which leads to determinants of infinite order; on the other hand, by considering an unknown function $\phi(x)$ (that is to say in last analysis a *continuous* infinity of unknowns) and seeking to determine it by the aid of equations where this function figures in integrals under the sign $\int$. Upon this second way Fredholm has embarked.

Let $K(x, y)$ be a function we call the *kernel*, the integral

$$\psi(x) = \int K(x, y)\phi(y)dy,$$

taken between fixed limits, may be regarded as a transform of $\phi(x)$ by a sort of linear transformation and be represented by $S\phi(x)$.

The integral equations may then be put under the form

$$(1) \qquad a\phi(x) + \lambda S\phi(x) = f(x),$$

where $f(x)$ is a given function, the equation is said to be of the first kind if the coefficient a is null, and of the second kind if this coefficient is equal to 1.

The relation (1) should be satisfied by all the values of y comprised in the field of integration; it is therefore equivalent to a *continuous* infinity of linear equations.

Fredholm has treated the case of the equations of the second kind; the solution then may be put under the form of the quotient of two expressions analogous to determinants and which are integral functions of λ. For certain values of λ, the denominator vanishes. We then can find functions $\phi(x)$ (called *proper functions*) which satisfy the equation (1) when we replace $f(x)$ in it by 0.

The result supposes that the kernel $K(x, y)$ is limited; if it is not, we are led to consider *reiterated* kernels; if we repeat n times the linear substitution S, we obtain a substitution of the same form with a different kernel $K_n(x, y)$; if one of these reiterated kernels be limited this suffices for the method to remain applicable by means of a very simple artifice. Now this happens in a great number of cases, as Fredholm has shown. The generalization for the case where the unknown function depends upon several variables and for that where there are several unknown functions is made without difficulty.

Fredholm then applied his method to the solution of Dirichlet's problem and to that of a problem in elasticity, thus showing how we may attack all questions of mathematical physics.

Such is the part of the first inventor; what now is Hilbert's? Consider first a finite number of linear equations; if the determinant of these equations is symmetric, their first members may be regarded as the derivatives of a quadratic form, and hence results for equations of this form a series of propositions very worthy of interest and well known to geometers. The corresponding case for integral equations is that where the kernel is symmetric, that is to say, where

$$K(x, y) = K(y, x).$$

This Hilbert takes hold of. The properties of quadratic forms of a finite number of variables may be generalized so as to apply to integral equations of this symmetric form. The generalization is made by a simple passing to the limit, but this passing presented difficulties which Hilbert overcame by a method admirable in its

simplicity, certainty and generality. The developments reached are *uniformly* convergent, but this uniformity presents itself under a new form which deserves to attract attention. In the developments appears an arbitrary function $u(x)$ (or several) and the remainder of the series when n terms have been taken is less than a limit depending only upon n and independent of the arbitrary function, provided this function is subject to the inequality

$$\int u^2(x)\,dx < 1,$$

the integral being taken between suitable limits. This is an entirely new consideration which may be utilized in very different problems.

Thus Hilbert obtains in a new way certain of Fredholm's theorems, but I shall stress above all the results which are most original.

In the first place, the denominator of Fredholm's expressions is a function of λ admitting only real zeroes, and this is a generalization of the elementary theorem relative to "the equation in S." Afterward comes a formula where enter under the sign $\int$ two arbitrary functions $x(s)$ and $y(s)$ which we should consider as the generalization of the elementary formulas which permit the breaking up of a quadratic form into a sum of squares.

But I hasten to reach the question of the development of an arbitrary function proceeding according to proper functions. Is this development, the analogue of Fourier's series or of so many other series playing a principal rôle in mathematical physics, possible in the general case? The sufficient condition that a function be capable of such development is that it can be put in the form $Sg(x)$, $g(x)$ being continuous. This is the final form of the resultant as Hilbert gives it in his fifth communication. In the first he was forced to impose certain restrictions; here we must mention the name of Schmidt, who in the interval had produced a work which helped Hilbert to free himself from these restrictions. The only condition imposed upon our function is capability of being put in the form $Sg(x)$, and at first blush this would seem sufficiently complex, but in a large number of cases and, for example, if the kernel is a Green's function, it only requires that the function possess a certain number of derivatives.

Hilbert was afterward led to develop his views in the following manner: he this time considers a quadratic form with an infinite number of variables and he studies its orthogonal transformations; this is as if he wished to study the different forms of the equation of a surface of the second degree in space of an infinite number of dimensions when referred to different systems of rectangular axes. To this effect he makes what he calls the resolvent form of the given form. Let $K(x)$ be the given form, $K(\lambda, x, y)$ the resolvent form sought, it will be defined by the identity

$$K(\lambda, x, y) - \tfrac{1}{2}\lambda \Sigma_r \frac{dK(x)}{dx_r} \frac{dK(\lambda, x, y)}{dx_r} = \Sigma x_r y_r$$

When the form $K(x)$ depends only upon a finite number of variables, the resolvent form presents itself as the quotient of two determinants which are integral polynomials in λ.

Our author applies to this quotient the procedures of passing to the limit which are familiar to him; the limit of the quotient exists even when those of the numerator and of the denominator do not exist.

In the case of a finite number of variables, $K(\lambda, x, y)$ is a rational function of λ and this rational function can be broken up into simple fractions. What becomes of

this decomposition when the number of variables becomes infinite? The poles of the function rational in λ may in this case or otherwise tend toward certain limit points infinite in number but discrete.

The aggregate of these points constitutes what our author calls the *discontinuous spectrum* of his form. They may also admit as limit points all the points of one or several sects of the real axis. The aggregate of these sects constitutes the *continuous spectrum* of the form.

The simple fractions corresponding to the discontinuous spectrum will make in their totality a convergent series, those corresponding to the continuous spectrum will change at the limit into an integral of the form

$$\int \frac{\sigma d\mu}{\lambda - \mu},$$

where the variable of integration μ is varied all along the sects of the continuous spectrum, and where σ is a suitable function of μ. The rational function $K(\lambda, x, y)$, therefore, has then as limit not a meromorphic function, but a uniform function with erasures. The decomposition into simple elements thus transformed remains valid. If the given form is *limited*, that is to say, if it can not pass a certain value when the sum of the squares of the variables is less than 1, we can deduce thence a way of simplifying this form by an orthogonal transformation, analogous to the simplification of the equation of an ellipsoid by referring this surface to its axes.

Among the quadratic forms we shall distinguish those which are *properly continuous* (vollstetig), that is to say, those whose increment tends toward zero when the increments of the variables tend simultaneously toward zero in any way. Such a form does not have a continuous spectrum and hence result noteworthy simplifications in the formulas.

Other theorems on the systems of simultaneous quadratic forms, on bilinear forms, on Hermite's form, extend likewise to the case of an infinite number of variables.

There was in this theory the germ of an extension of Fredholm's method to kernels to which the analysis of the Swedish geometer was not applicable, and scholars of Hilbert should bring out this fact. However that may be, Hilbert first applied himself to extending his way of looking at integral equations to the cases where the kernel is unsymmetric. For this purpose he introduces any system of orthogonal functions, conformably to which it is possible to develop an arbitrary function by formulas analogous to that of Fourier. In place of an unknown function, he takes as unknowns the coefficients of the development of this function, an integral equation can thus be replaced by a system of a *discrete* infinity of linear equations between a *discrete* infinity of variables.

The theory of integral equations is thus attached, on the one hand, to the ideas of von Koch on infinite determinants, and, on the other hand, to the researches of Hilbert we have just analyzed and where the essential rôle is played by functions dependent upon a discrete infinity of variables.

To each kernel will correspond thus a bilinear form dependent upon an infinity of variables. If the kernel is symmetric, this bilinear form is symmetric and may be regarded as derived from a quadratic form. If the kernel satisfies the conditions stated by Fredholm, we see that this quadratic form is properly continuous and consequently does not have a continuous spectrum. This is a way of reaching Fredholm's results, and however indirect it may be, it opens entirely new views of the profound reasons for these results and hence on the possibility of new generalizations.

Integral equations lend themselves to the

solution of certain differential equations whose integrals are subject to certain conditions as to the limits, and this is a very important problem for mathematical physics. Fredholm solved it in certain particular cases and Picard generalized his methods. Hilbert made a systematic study of the question.

Consider an integral equation

$$\Delta^u = f,$$

where u is an unknown function of one or several variables, f a known function and Δ any linear differential expression. This equation with the same right as an integral equation may be considered as an infinite system of linear equations connecting a continuous infinity of variables, as a sort of linear transformation of infinite order, enabling us to pass from f to u. If we solve this equation, we find

$$u = Sf,$$

$S(f)$ this time presenting itself under the form of an integral expression.

Then Δ and S are the symbols of two linear transformations of infinite order inverse one to the other. The kernel of this integral expression $S(f)$ is what we call a *Green's function*. This function was first met in Dirichlet's problem, then it was Green's function properly so called, too familiar to be stressed, we had already obtained different generalizations of it. To have given a complete theory belongs to Hilbert. To each differential expression Δ, supposed of the second order and of elliptic type, to each system of conditions as to the limits, corresponds a Green's function. We cite the formation of the Green's functions in the case where we have only one independent variable and where they present themselves under a particularly simple form, and the discussion of the different forms the conditions as to the limits may assume. That settled, suppose we have solved the problem in the case of an auxiliary differential equation differing little from that proposed and anyhow not differing from it by the terms of the second order, we can then by a simple transformation reduce the problem to the solution of a Fredholm equation where the rôle of kernel is played by a Green's function relative to the auxiliary differential equation. However, the consideration of this auxiliary equation, the necessity of choosing it and solving it being capable of still constituting an embarrassment, in his sixth communication Hilbert frees himself from it. The differential equation is transformed into a Fredholm equation where the rôle of kernel is played by a function our author calls *parametrix*. It is subject to all the conditions defining Green's function, one alone excepted, the most troublesome, it is true, it is not constrained to satisfy a differential equation, it remains therefore in a very large measure arbitrary. The transformation undergone by the differential equation is comparable to that experienced by a system of linear equations if we replace the primitive variables by linear combinations of these variables suitably chosen. The method is nowise restricted to the case where the differential equation considered is adjoint to itself.

Hilbert examined in passing a host of questions relative to integral equations and showed the possibility of their application in domains the most varied. For example, he extended the method to the case of a system of two equations of partial derivatives of the first order of the elliptic type, to *polar* integral equations, that is to say, where the coefficient a in the integral equation (1) in place of being always equal to 1 is a function of x and in particular is equal now to $+1$, now to -1.

He has applied the method to the problem of Riemann for the formation of func-

tions of a complex variable subject to certain conditions as to the limits, to the theorem of oscillations of Klein, to the formation of fuchsian functions, and in particular to the following problem to determine λ so that the equation

$$\frac{d}{dx}\left[(x-a)(x-b)(x-c)\frac{dy}{dx}\right]+(x+\lambda)y=0$$

may be a fuchsian equation

One of the most unexpected applications is that Hilbert makes to the theory of the volumes and surfaces of Minkowski, and by which he connects with Fredholm's method a question important for those who interest themselves in the philosophic analysis of the fundamental notions of geometry

DIRICHLET'S PRINCIPLE

We know that Riemann with a stroke of the pen proved the fundamental theorems of Dirichlet's problem and conformal representation, grounding himself on what he called Dirichlet's principle, considering a certain integral depending upon an arbitrary function U, and which we shall call Dirichlet's integral, he showed that this integral can not become null and from this he concludes that it must have a minimum, and that this minimum can be reached only when the function U is harmonic This reasoning was faulty, as has since been shown, because it is not certain that the minimum can be actually reached, and if it is, that it can be for a continuous function.

Yet the results were exact; much work has been done on this question; it has been shown that Dirichlet's problem can always be solved, and it actually has been solved; it is the same with a great number of other problems of mathematical physics which formerly would have seemed attackable by Riemann's method. Here is not the place to give the long history of these researches; I shall confine myself to mentioning the final point of outcome, which is Fredholm's method

It seemed that this success had forever cast into oblivion Riemann's sketch and Dirichlet's principle itself Yet many regretted this, they knew that thus we were deprived of a powerful instrument and they could not believe that the persuasive force which in spite of all Riemann's argument retained, and which seemed to rest upon I know not what adaptation of mathematical thought to physical reality, was actually only a pure illusion due to bad habits of mind. Hilbert wished to try whether it would not be possible, with the new resources of mathematical analysis, to turn Riemann's sketch into a rigorous proof See how he arrived at it, consider the aggregate of functions U satisfying proposed conditions, choose in this aggregate an indefinite series of functions S, such that the corresponding Dirichlet integrals tend in decreasing toward their lower limit. It is not certain that at each point of the domain considered this series S is convergent, it might oscillate between certain limits But we can in S detach a partial series S_1 which is convergent at a point M_1 of the domain, in S_1, detach another partial series S_2 which shall always be convergent at M_1, but which, moreover, shall also be convergent at M_2 So continuing, we shall obtain a series which will be convergent at as many points as we wish, and by a simple artifice we from this deduce another series which will be convergent at all the points of a countable assemblage, for example at all the points whose coordinates are rational. If then we could prove that the derivatives of all the functions of the series are less in absolute value than a given limit, we might conclude immediately that the series converges uniformly in the whole domain and the application of the rules of the calculus

of variations would no longer present special difficulty

To establish the point remaining to be proved, Hilbert has used two different artifices, he has not developed the first as completely as would be desirable, and has attached himself especially to the second This consists in replacing the proposed function u by the function v, which comes from it by a double quadrature and of which it is the second derivative with regard to two independent variables The derivatives of v being the first integrals of u, we can assign them an upper limit, by the help of certain inequalities easy to prove Only it is necessary to be resigned to a new circuit and to an artifice simple however to apply to this new unknown function v the rules of the calculus of variations which apply so naturally to the function u

It is needless to insist upon the range of these discoveries which go so far beyond the special problem of Dirichlet It is not surprising that numerous investigators have entered the way opened by Hilbert We must cite Levi, Zaremba and Fubini, but I think we should signalize before all Ritz, who, breaking away a little from the common route, has created a method of numeric calculus applicable to all the problems of mathematical physics, but who in it has utilized many of the ingenious procedures created by his master Hilbert

Recently Hilbert has applied his method to the question of conformal representation. I shall not analyze this memoir in detail I shall confine myself to saying that it supplies the means of making this representation for a domain limited by an infinite number of curves or for a simply connected Riemann surface of an infinity of sheets. This therefore is a new solution of the problem of the uniformization of analytic functions

DIVERS

We have passed in review the principal research subjects where Hilbert has left his trace, those for which he shows a sort of predilection and whither he has repeatedly returned, we must mention still other problems with which he has occupied himself occasionally and without insistence I think I should confine myself to giving in chronologic order the most striking results he has obtained of this sort

Excepting the binary forms, the quadratic forms and the biquadratic ternary forms, the definite form most general of its degree can not be broken up into a sum of a finite number of squares of other forms

By elementary procedures may be found the solutions in integers of a diophantine equation of genus null

If an integral polynomial depending upon several variables and several parameters is irreducible when these parameters remain arbitrary, we may always give these parameters integral values such that the polynomial remains irreducible

Consequently there always exist equations of order n with integral coefficients and admitting a given group

The fundamental theorem of Dedekind about complex numbers with commutative multiplication may be easily proved by means of one of the fundamental lemmas of Hilbert's theory of invariants.

The diophantine equation obtained by equating to ± 1 the discriminant of an algebraic equation of degree n has always rational solutions, but save for the second and the third degrees has no integral solutions.

Among the real surfaces of the fourth order, certain forms logically conceivable are not possible; for example, there can not be any composed of twelve closed surfaces simply connected or of a single surface with eleven perforations.

CONCLUSIONS

After this recital, a long commentary would be useless We see how great has been the variety of Hilbert's researches, the importance of the problems he has attacked We shall signalize the elegance and the simplicity of the methods, the clearness of the exposition, the solicitude for absolute rigor In seeking to be perfectly rigorous one risks at times being long, and this is not to buy too dear a correctness without which mathematics would be nothing But Hilbert has known how to avoid the tedium of such diffuseness for his readers in never letting them lose from view the guiding thread which has served him to orient himself We always easily see by what chain of ideas he has been led to set himself a problem and find its solution

We realize that, more analyst than geometer in the ordinary sense of the word, he nevertheless has seen at one view the totality of his work before distinguishing details and he knows how to give his reader the advantage of this all-embracing vision

Hilbert has had a tremendous influence upon the recent progress of the mathematical sciences, not alone by his personal work, but by his teaching, by the counsel he has given to his scholars and which has enabled them to contribute in their turn to this development of our knowledge by using the methods created by their master.

There is no need, so it seems, to say more in justification of the decision of the commission which has unanimously awarded to Hilbert the Bolyai prize for the period 1905–1909.

M. Poincaré

THE WILLARD GIBBS MEDAL

In the early part of 1909 Mr. William Converse, of Chicago, proposed to the Chicago Section of the American Chemical Society to found a gold medal to be awarded annually by the Section Mr. Converse stated that the object of his proposition was to stimulate interest in the work of the Section and of the society at large and to encourage the highest ideals of the science in their members The Section gladly welcomed and accepted the offer made It was proposed to name the medal after the most eminent chemist America has given to the science, and the consent of Mrs Van Name, the surviving sister of Willard Gibbs, having been secured, the medal founded by Mr Converse was named the Willard Gibbs Medal After various plans had been suggested and discussed, the Section decided that the medal should be awarded annually, by invitation, rather than by competition and the following rules were adopted for the award.

RULES FOR THE AWARD OF THE WILLARD GIBBS MEDAL, FOUNDED BY WILLIAM A CONVERSE

1 A gold medal shall be awarded annually by the Chicago Section of the American Chemical Society at its May meeting, which meeting shall be open to the public

The medal is to be known as the Willard Gibbs Medal founded by William A Converse

The award shall be made according to the rules here set forth and made a part of the by-laws of the Chicago Section

2 The award shall be made by a two-thirds vote of a jury of twelve, to anybody who because of his eminent work in and original contributions to pure or applied chemistry, is deemed worthy of special recognition by the jury

3. A condition of the award shall be that the recipient of the medal shall deliver an address upon a chemical subject of his own selection and satisfactory to the jury at the May meeting of the Chicago Section of the American Chemical Society. He shall be notified of the award three months in advance of this meeting by the chairman of the Chicago Section.

4. The jury of the award, to be known as the Jury of the Willard Gibbs Medal, shall consist of twelve members, six of them to be members of the Chicago Section. The chairman of the Chicago Section shall be chairman of the jury, but shall have no vote.

5. Four members of the jury shall be elected each year to serve three years, in the same manner

and at the same time as the officers of the Chicago Section

At the first election of the jurors of the Willard Gibbs Medal, to be held in 1911, four jurors shall be elected to serve a term of one year, four to serve a term of two years and four to serve a term of three years. Of each four elected, two shall be from the Chicago Section

6 At the call of the chairman of the Chicago Section the jury shall begin its deliberation on January 2 of each year

Each member of the jury shall be entitled to place in nomination the names of two candidates The voting shall then be on these candidates

The four names receiving the highest number of votes on the first ballot shall be retained, the others rejected

If of the four names retained, none receives a two thirds vote on the second ballot, the two receiving the fewest votes shall be dropped. If on further balloting the committee finds it impossible to make a selection by a two thirds vote, it will report to the section, which will proceed to elect the recipient of the medal, but if any candidate receives a two thirds vote of the committee, his election shall be final and shall be so reported to the section

7. It is desired that the paper or address, if suitable, be published in one of the publications of the American Chemical Society.

8 The executive committee of the Chicago Section shall have the power to decide any question not specifically covered by these rules

9. The Chicago Section shall have the power to change or amend these rules in the same manner as the by-laws of the section

For the first year of the foundation, 1911, by special amendment of the rules of the Section a special jury of award was elected, consisting of the following members S A Mather, chairman of the section and president of the Thorkildsen-Mather Co, W. Brady, chief chemist of the Illinois Steel Co.; D K French, secretary of the section and chemist of the Dearborn Drug and Chemical Co.; W. Hoskins, of Mariner and Hoskins, Professor John H. Long, of the Northwestern University Medical School; A. Lowenstein, chief chemist of Nelson Morris & Co.; Professor H. McCormick, of Armour Institute; Professor H. N. McCoy, of the University of Chicago; W D. Richardson, chief chemist of Swift & Co; Professor Alexander Smith, of the University of Chicago, and president of the American Chemical Society, and Professor Julius Stieglitz, of the University of Chicago By a unanimous vote the jury decided to award the first medal to Professor Svante Arrhenius for his fundamental work on the theory of electrolytic dissociation

The medal was presented to Dr. Arrhenius on the evening of May 12, after a banquet which was attended by over 200 members and guests of the section The formal program of the evening included the following addresses "International Bonds of Science," by Harry Pratt Judson, president of the University of Chicago, "Chemistry and Commerce," by Mr Wheeler, president of the Association of Commerce of Chicago, "The Willard Gibbs Medal," by S A Mather, chairman of the Chicago Section of the American Chemical Society, "The Presentation of the Willard Gibbs Medal to Dr Arrhenius," by Alexander Smith, president of the American Chemical Society, and "The Willard Gibbs Address," by the medallist, Svante Arrhenius, on "The Theory of Electrolytic Dissociation." The last address gave, in outline, the history of the discovery of the theory of electrolytic dissociation, it formed, on the one hand, an intensely interesting record of the birth of a great idea and theory, of its early difficulties and its final triumph; and, on the other hand, it presented a picture of the struggles, progress and development of the genial discoverer of the theory

The address will be published under the auspices of the Chicago Section of the American Chemical Society

SCIENTIFIC NOTES AND NEWS

DR. SAMUEL H. SCUDDER, of Cambridge, eminent for his contributions to entomology, especially lepidoptera and fossil insects, died on May 17, aged seventy-four years.

DURING his recent visit to Washington at the time of the annual meeting of the National Academy of Sciences, Sir John Murray presented a fund of six thousand dollars to

the academy for the purpose of founding an Alexander Agassiz gold medal which shall be awarded to scientific men in any part of the world for original contributions to the science of oceanography.

AT the twentieth annual commencement of Stanford University, to be held from May 17 to 22, a portrait of President Jordan will be presented to the university.

COLONEL WILLIAM GORGAS, U. S. A., head of the sanitary forces on the Isthmus of Panama, received the honorary degree of doctor of laws from Tulane University at its annual commencement on May 17.

PROFESSOR PAUL H. HANUS, head of the department of education at Harvard University, has been chosen to take general charge of the investigation of the New York public school administration conducted by the School Inquiry Committee.

PROFESSOR C. F. MABERY has resigned the professorship of chemistry in Case School of Applied Science, which he has occupied since 1883.

DR. J. REIN, professor of geography at Bonn, has celebrated the fiftieth anniversary of his doctorate.

DR. R. FICK, professor of anatomy at Innsbruck, has been elected a corresponding member of the Royal Society of Physicians of Vienna.

THE Pharmaceutical Society has elected the following honorary members: Professor W. E. Dixon, F.R.S., professor of pharmacology, King's College, London; Dr. Adolph Engler, director, Botanical Museum, Berlin; Professor Percy F. Frankland, F.R.S.; M. Eugène Léger, pharmacien en chef de l'Hôpital St. Louis, Paris; Lieutenant-Colonel D. Prain, F.R.S., director of Royal Gardens, Kew; and Dr. Ludwig Radlkofer, professor of botany, University of Munich.

THE *Bulletin* of the American Mathematical Society states that the eminent mathematician, Professor Gaston Darboux, of the University of Paris, being about to complete his fiftieth year of service as a teacher in the system of public instruction of France, it is proposed by a large international group of his mathematical co-workers, friends and former pupils to commemorate this anniversary by presenting to Professor Darboux a gold medal bearing his portrait, and an appropriate address signed by the participants. All mathematicians are invited to share in rendering this honor to Professor Darboux. Copies of the medal, in reduced size, will be struck. Subscribers of twenty-five francs will receive a copy in bronze, subscribers of fifty francs a copy in silver. Subscriptions should be sent to Professor Cl. Guichard, secretary of the Faculté des Sciences.

DR. JOHANNES HARTMANN, professor of astronomy at Gottingen and director of the university observatory, has been called to be director of the Argentine Observatory at La Plata.

PROFESSOR C. H. HITCHCOCK, emeritus professor of geology at Dartmouth College, has come east from Hawaii for the purpose of completing his field work for the Geological Survey of Vermont. Some attention will also be paid by him to ichnological studies. His address will be at Hanover, N. H., for the summer.

PROFESSOR ALEXANDER GRAHAM BELL returned on May 8 from a trip around the world.

DR. T. C. MENDENHALL, formerly of the Ohio State University and later president of Worcester Polytechnic Institute, is on a visit to Japan, where from 1878 to 1881 he occupied the chair of physics in Tokyo University.

DR. JOHN C. BRANNER, of Stanford University, is the head of a scientific expedition to the coast of Brazil, which sailed from New York on April 18 for Para.

MR. WILFRED H. OSGOOD, of the Field Museum of Natural History, has returned from three months work in Venezuela and Columbia, having obtained important collections of birds and mammals, including a small series of the rare marsupial, *Cænolestes*, a living representative of the family Epanorthidæ.

WE learn from the *Auk* that Mr A C Bent, of Taunton, Mass, is organizing an expedition to the Aleutian Islands for the purpose of making a thorough biological survey of that interesting region, covering practically the whole of the summer season Negotiations are now on foot to secure the use of a revenue cutter to take the party, which will consist of three scientific men in addition to Mr Bent Mr Rollo H Beck, known for his work in the Galapagos Islands and along the coast of California, has already been engaged, and it is probable that the United States National Museum and the Biological Survey will each send a representative

PROFESSOR W F. WATSON, who has held since 1890 the chair of chemistry and biology at Furman University, Greenville, S C, has resigned, and will spend four years in a tour around the world.

DR. SVANTE ARRHENIUS lectured at the College of the City of New York on May 17 and at Columbia University on May 18 On May 15 he lectured on the J C Campbell foundation of the Sigma Xi Society of the Ohio State University

DR WALTER B CANNON, professor of physiology in the Harvard Medical School, will give the annual address before the graduating class of the Yale Medical School at the approaching commencement

PROFESSOR JOHN M. COULTER, head of the department of botany of the University of Chicago, will give an address before a joint meeting of the Sigma Xi and Phi Beta Kappa fraternities on June 12, as a part of the program of commencement week at the University of Illinois.

PROFESSOR W. W. OSTERHOUT addressed the Biological Society of Smith College on May 18 on "Some Aspects of the Action of Mineral Salts on Plants"

DR. E. E BARNARD, of Yerkes Observatory, lectured on "Photographic Revelations in Astronomy" before the Dayton Astronomical Society on May 10 and before the Cincinnati Astronomical Society on May 12.

AT the first annual meeting of the Cincinnati Society, held May 12, the following officers were elected Dr Lisle Stewart, president, W C Cooder, vice-president, Robert H Correy, secretary, A D Fisher, treasurer, A D Alcorn, P B Evens, J D Griese, A P. Henkel, C H Norton, M C Slutes, directors President Taft was unanimously elected an honorary member Sixty-five men and women joined as charter members This society expects to interest itself particularly with astronomical and astrophysical research

WE learn from *Nature* that a committee of the Geological Society, London, has been formed to secure the means of providing a memorial to the late Professor T Rupert Jones, F R S, in aid of his widow and daughters The late Professor Jones was never in receipt of more than a very moderate income, and received only a small pension upon his retirement thirty years ago from the post of professor of geology in the Royal Military College, Sandhurst.

THE ninety-fourth annual meeting of the Swiss Scientific Society, will be held this year at Solothurn, from July 30 to August 2, under the presidency of Dr A Pfaehler In addition to the general sessions for which a number of addresses of general interest are arranged, there meet with the association the Swiss societies for botany, chemistry, geology, mathematics, physics and zoology Foreign men of science are especially invited to be present at the meetings

THE H F. KIETH COMPANY, of Boston, have given $5,000 to the Massachusetts Institute of Technology, for a research on the decomposition and general wholesomeness of eggs and for an investigation of the bacterial and chemical contents of the product under varying conditions

Two collections of birds have been placed on deposit in the American Museum of Natural History. One of these, the property of Dr. Jonathan Dwight, Jr., of New York City, numbers about 30,000 specimens, ranking as one of the largest private collections in this country. It is especially valuable in showing

plumages and molts of North American species. The second collection belonging to Dr. Leonard C. Sanford, of New Haven, Connecticut, contains about 400 specimens, largely non-passerine birds, and includes rare species especially among the albatrosses and petrels, some of which are not represented in the American Museum collections.

AN arrangement has been concluded between the German and English governments and the Marconi Company by which the weather observations transmitted by wireless telegraphy from ships on the Atlantic will be made mutually available to the English and German Meteorological Offices. Experiments in this direction were made in 1909. The new arrangement is expected to come into force by next year at latest. The observations will be transmitted to the Meteorological Office in London, to the Marine Observatory at Hamburg and to the Meteorological Station at Aachen.

IN Bulletin 420 of the United States Geological Survey, entitled "Economic Geology of the Feldspar Deposits of the United States," by Edson S. Bastin, there are descriptions of the many feldspar deposits in the country and the extent to which the industry has grown. The principal consumers of feldspar are manufacturers of pottery, enamel ware, enamel brick and electric ware. The trade demands that feldspar for use in pottery be nearly free from iron-bearing minerals (biotite, garnet, hornblende, black tourmaline, etc.) and that it contain little if any muscovite. Feldspar is also used in the manufacture of emery and carborundum wheels, as a flux to bind the abrading particles together. Small quantities of feldspar are used in the manufacture of opalescent glass and carefully selected pure feldspar is used in the manufacture of artificial teeth. Some is used in scouring soaps and window washes, the fact that feldspar is slightly softer than glass rendering these soaps less liable to scratch windows or glassware than the soaps in which quartz is the abrasive substance. Two firms in New York and one in Connecticut crush feldspar for poultry grit and for use in the manufacture of ready roofing. In a number of the feldspar quarries garnets, green tourmalines and aquamarines (beryl) of gem quality are found, but seldom in such quantity as to warrant mining for the gems alone. Mr. Bastin mentions a feldspar quarry in Connecticut where some of the cavities that yielded gem tourmalines were as large as a bushel basket. At another quarry in the state a large transparent green tourmaline about seven inches long was found. This stone is now in the museum of the Wesleyan University at Middletown, Conn. One pocket in the same quarry contained a large crystal weighing several pounds, of pale-blue to pale-green color, the tints being similar to those observed in some aquamarines. Unfortunately, this crystal was much shattered in the blasting, but the fragments have yielded a number of small cut gems of great beauty.

UNIVERSITY AND EDUCATIONAL NEWS

GOVERNOR FOSS has signed the bill by which the Massachusetts Institute of Technology will receive \$100,000 annually from the state for ten years. By the terms of the measure the Institute will maintain 80 free scholarships to be apportioned among the 40 senatorial districts of the state.

THE California legislature has passed a bill which has been recently signed by the governor appropriating \$25,000 for a soils laboratory building, equipment and other improvements at the Citrus Experiment Station. About \$1,500 of this amount will be used in improving the irrigation system, \$2,500 to complete the title for building site and nursery grounds, about \$2,000 for incidentals, leaving \$19,000 for building and equipment. The work of this laboratory is to be confined to the study of citrus soils from their chemical, physical and biological phases.

THE legislature of Hawaii, just adjourned, appropriated \$75,000 for a new building for the College of Hawaii and \$20,000 for maintenance expenses. The committee of education favored the adoption of the plans that have been drawn up for the development and

embellishment of the campus and grounds These grounds are located in Manoa, a suburban valley with both mountain and sea views, and comprise about ninety acres Sixty acres were purchased and thirty acres were set aside by the government The total grounds with its water has a market value of about $125,000

M ALBERT KAHN, of Paris, who has established traveling fellowships in several foreign countries, has given $2,500 for such a fellowship in the United States It is expected that the fellow selected will travel around the world giving a year to the trip Selection of the fellow will be made by the trustees, who are Edward D Adams, Nicholas Murray Butler, Charles W Eliot, Henry Fairfield Osborn and Charles D Walcott, and they are to choose preferably professors in isolated southern and western institutions

DR H. Y BENEDICT, professor of applied mathematics and director of the department of extension of the University of Texas, has been made dean of the College of Arts

AT the University of Pennsylvania Dr Richard M Pearce has been transferred from the chair of pathology to that of experimental pathology, and Dr Allen J Smith has been transferred from the chair of tropical diseases to that of pathology, formerly occupied by him.

DR. LUTHER WILLIAM BAHNEY, assistant professor of metallurgy at Leland Stanford University, has been appointed assistant professor of mining and metallurgy in the Sheffield Scientific School, Yale University

DR. CLARENCE A. PIERCE, of Cornell University, has been appointed assistant professor of theoretical electrical engineering at the Worcester Polytechnic Institute to succeed Dr. George R. Olshausen, who has resigned after four years of service

DR. WALTER S. TOWER, assistant professor of geography in the University of Pensylvania, has been called to the University of Chicago.

DR. J. FRANK DANIEL has been promoted to be assistant professor of zoology in the University of California.

DISCUSSION AND CORRESPONDENCE

THE LAW THAT INHERES IN NOMENCLATURE

DR. JORDAN'S answer[1] to my inquiry,[2] "Whether there is not a better way of disposing of our nomeclatural trouble than first making it as burdensome as possible and then making it permanent?" is, if I understand him aright, that, alas, there is none, at least, there is none yet in sight, or likely to appear. Hence it were better to take up the burden cheerfully, and begin getting used to it

Whether one be pleased with this prospect or not, he must be grateful for Dr Jordan's clear and forceful statement of certain guiding principles. This, for example, seems to me to go to the heart of the matter under discussion

"A writer dealing with scientific names must either call an animal or plant what he pleases, or else he must conform to regulations inherent in the nature of his work Arbitrary rules will soon be disregarded The necessary regulations are those which future workers will approve, and we who are working in the infancy of taxonomy must lay foundations on which the future can build" With this we may all agree, though we may hold somewhat different views as to what is the law that inheres in the nature of our work, and as to what rules are arbitrary

Surely no argument is needed against a return to the loose nomenclatural methods of the past I protest against the implication that I have advocated anything of the sort. On the contrary, I have advocated the strictest application of the laws that have been evolved by our past nomenclatural experience. I would accept a list of names exactly as furnished by the best historical knowledge that could be brought into service in producing it. And then, because such a system would be more than human nature can bear, more than language can use, and more than our science can make its best progress under, I would provide for general use a terminology giving expression to the same system in simpler form, with fewer, briefer and simpler names, and

[1] SCIENCE, March 10, 1911.
[2] SCIENCE, September 2, 1910.

symbols. That is the whole of it. No plan for solving zoological problems by rule is proposed, only a plan for conserving time and energy, offered in the belief that the purely clerical work of biological science might be accomplished with less waste. The simpler system would stand in the same relation to the existing system as that in which the Linnæan names have stood to the long descriptive phrases that preceded them.

To be sure, this plan, which allows choice of names (one out of a score more or less in every group), does not necessitate that the oldest one shall be forced into general use in the new system: rather, it leaves the selection to those most competent, most interested and most responsible for the future in each group. This feature may hold the derogation of democracy to which Dr. Jordan refers, but if so, I do not understand what sort of a democracy systematic zoology is considered to be. Is a law of priority its only possible standard of equality? I profess to be a democrat, and, in a very small way, a systematist, yet I confess I never heard of anything like this. May not this democracy abide the recognition of merit? Is it already irrevocably bound up with a statute of nomenclatural primogeniture? Does the determination of priority in and of itself necessitate that all good democrats must acclaim the restoration of lost names to the places they once transiently occupied in spite of all that may have happened in the intervening years?

I have myself long pursued priority in the hope of names that would be both stable and usable. I have even advocated the forcing of prior forgotten names back into general nomenclature. I did so as long as mere temporary convenience seemed at stake. I did so while names doubled in length, trebled in absurdity and quadrupled in number. I did so until family names began to fall and to be set up again in exchanged places. I did so until I became unable to read the literature in several groups of which I had once been a student, or to converse with modern students of those groups. I did so until it became well nigh impossible for me to give to my classes intelligible references to the literature they most needed to consult in their work.[3] And

[3] Recently, while providing tables for the work of a small class in limnology, I encountered the following situation in aquatic diptera. Half of the names of dipterous families containing aquatic larvæ have been victims of the rule of priority. Here are the names of the families of our fauna, as found in all the text books, manuals, monographs and general reference books:

Psychodidæ	* Leptidæ
* Ptychopteridæ	Empididæ
Tipulidæ	x * Stratiomyiidæ
x * Blepharoceridæ	Syrphidæ
Dixidæ	* Borboridæ
* Chironomidæ	Ephydridæ
Culicidæ	x * Cordyluridæ or
* Simuliidæ	* Scatophagidæ
Tabanidæ	Sciomyzidæ

Only those unmarked in the list remain unchanged. Of the others, three (marked x) have been changed in spelling only, return to an incorrect or inelegant form being required in this line of progress. One of these names, Cordyluridæ, is in less common use than Scatophagidæ, but Scatophaga also falls. In addition to this, the well known names *Syrphus* and *Sciomyza* have been shifted to designate new groups of species in their respective families. So, also, has *Corethra* within its subfamily. All these familiar groups will now bear unfamiliar names.

Now, perhaps, a better democrat than I would have adopted all these changes willingly and pursued priority to the bitter end. But I did not. I wished my class to use the literature that has grown up about the names *Corethra, Chironomus, Simulium, Eristalis*, etc., names that are the subjects of books, of memoirs and of classic investigations in many fields of biology, and that have nowhere any uncertain meaning. As a teacher I could not afford the time and effort necessary to explain to rational young people why the "interests of taxonomy" require that *Corethra* or *Syrphus* be removed from their accustomed places after one hundred years, and used to designate entirely different groups of flies. In fact, I can not explain this; nor why, if the zoologists of the world have been able to agree on a law of priority, they might not yet be able to agree upon something less distressing.

Any one who speaks of this as a matter of *temporary* inconvenience surely is thinking in terms of geologic time.

then I began to entertain doubts as to the approval of posterity, the best kind of foundations, etc I began to lose faith in the law of priority as a cure-all for nomenclatural ills For the real burden of nomenclature will be but little altered by the strictest application of this law At worst (and surely the worst is now in sight) it will have added but a little dead weight of stupid and unnecessary confusion—so little, indeed, it would hardly be noticeable were not the load already at the endurance limit With all the arduous labor now required of any youth for gaining even an elemental conception of the world's accumulated store of knowledge, why should any man, even though a profound scholar, familiar with the intricacies of his own field, so far forget or minimize the difficulties of the long way by which he has come as to be willing to leave the path harder for the next comer. Ought not the way that leads to a working knowledge of plants and animals to be as easy and plain as we can possibly make it? I think so And so thinking, I ventured to propose, after long consideration, the simplification that is now under discussion

My plan would accept the facts of nature as they are—exceedingly complicated They are not more complex under one system than under another And it is a great error to assume that because facts are numerous and relations complex, the method of handling them must be equally so

My plan would accept human nature as it is—exceedingly prone to differences of opinion, yet, withal, able often to agree upon such matters as dates of publication.

My plan would accept the results of the application of the law of priority *in toto*, conserving all the good work that has been done by the zoologists of the world in their search of early literature. It would keep the results of this work forever accessible, without making of its by-products stumbling blocks in the way of beginners, of general students, and of the increasing thousands who may have an interest in biological sciences This work is of great historic value It is worth while to have all the old and unused names set in their proper order and sequence But to have any such of them as have lain buried during the growth of a great literature, used when exhumed to replace the names about which that literature has grown, making its treasures less accessible, is a lamentable abuse of the historic method[4] Let us accept the good work that has been done in determining priority at its historical value, and then let us use it like rational beings for our assistance, without making it a source of embarrassment for future generations

My plan would accept the Linnæan system as it is, recognizing species as real entities that have received and that will continue to receive names Were Linnæus resurrected today, he might have difficulty in recognizing his own system, in its present dropsical condition Those who value it so highly should at least remember that, whatever it has become, it was in the beginning simply and solely an effort at simplification of nomenclature

The matter of numbering species is so simple it is hard to understand how any difficulty is found in applying it Given a list of the names now recognized in any group written down in their original form and in their historic sequence, any common clerk could affix the numerals correctly. Their stability would be assured by the only means whereby anything becomes stable—by adoption and use Any one who will read my proposal with reasonable care will see (1) that it accepts every name exactly as given by its author, and finds a place for it in its proper sequence; (2) that it matters not at all where we begin numbering, and (3) that it matters not at all whether *Balanoglossus* and the tunicates are fishes or not.

I regret Dr. Jordan did not see these things, for then he might have saved space for a statement of the inherent law of nomenclature. Formulation of it is badly needed.

[4] My proposal, however, was to let the principal workers in any group decide upon the names to be used in it. If those who study lancelets do not wish to use the name *Amphioxus*, neither do I wish to use it.

Elsewhere real progress is found in the direction of simplification, which makes for convenience, saves time, and meets the limitations of memory by instituting more concise methods of making records. Does the law that inheres in nomenclature differ so much from that which obtains in all other vast accumulations of facts? If so, let us have a statement of it, so that we may, by understanding it, attain to acquiescence in the inevitable.

JAMES G. NEEDHAM
CORNELL UNIVERSITY

ON EVIDENCE OF SOMA INFLUENCE ON OFFSPRING FROM ENGRAFTED OVARIAN TISSUE

TO THE EDITOR OF SCIENCE: In publication No. 144 of the Carnegie Institution of Washington entitled, "On Germinal Transplantation in Vertebrates," by Castle and Phillips, issued March 14, 1911, an attempt is made to overthrow my experiments on transplantation of ovaries in fowls,[1] and Magnus's[2] experiments of similar character on rabbits, and to establish a claim to priority in the demonstration that offspring may result from transplanted ovaries; and the effect, if any, of soma influence on such offspring. Therefore, I feel it incumbent to call attention briefly to certain of the statements in order that no misunderstanding may result. Since my papers with the experiments are readily available, I shall avoid all unnecessary repetition.

In a word, the situation is as follows: By exchanging the ovaries of fowls and breeding the fowls, I obtained results which seem to show that the transplanted ovaries preserved their reproductive function, and the resulting offspring presented evidence of soma or foster-mother influence. The results are given in detail in my several papers. I may add that since I had no allegiance with any school of theorists, I was not involuntarily partial in observing and recording the results. Whether the results would substantiate either or neither of the theories built largely upon speculation as to the relationship of reproductive tissues to their environment, or whether the character of the offspring would conform to Mendel's results of studies of inheritance in peas, gave me no concern.

The primary object of the experiments was to determine if an engrafted ovary might retain its reproductive function. Therefore, an answer to the question was obtained. And incidentally information on soma influence was secured. Following this, it seemed of additional interest to reverse the matings of the parent stock. And also, by breeding, to study the character of the offspring from the offspring obtained from engrafted ovaries. Unfortunately before this was accomplished, the experiments were terminated by an outbreak of disease among the fowls. But I did not consider then, nor have I since come to believe, that the character of the offspring of the second generation could do more than indicate whether or not soma influence might be evident in the character of the offspring of this generation, that is, the grand chicks. But owing to a degree of familiarity with the general principles of physiological experimentation and interpretation, from the beginning I saw the limitations to the absoluteness of any evidence that might be obtained by continuation of such experiments. For example, before drawing the provisional conclusions in the announcement of my results, the statement was made that "more data must be had on these points before definite conclusions can be drawn."[3] Apparently Castle has

[1] "Results of Removal and Transplantation of Ovaries in Chickens," presented before the American Physiological Society in connection with the seventh meeting of the Congress of American Physicians and Surgeons, Washington, D. C., May 7–9, 1907 (*American Journal of Physiology*, 1907, XIX., xvi–xvii). "Further Results of Transplantation of Ovaries in Chickens," *Journal of Experimental Zoology*, 1908, V., 563. "On Graft Hybrids," presented before the American Breeders' Association, Omaha, December, 1909. "Survival of Engrafted Tissues. I. (A) Ovaries and (B) Testicles," *Journal of Experimental Medicine*, 1910, XII., 269.

[3] *Journal of Experimental Zoology*, June, 1908, V., p. [illegible].

overlooked this statement. And I may say that all subsequent statements regarding my results have been made from the same standpoint.

In attempting to interpret my results from the Mendelian standpoint, to overcome the difficulty in concluding that in no instance the offspring were derived from engrafted ovarian tissue, Castle can only see his way clear by speculating as to the result that might have followed had I employed two white cocks in the matings, one cock being a half-breed. But he assumes that only one white cock was used, for, as he points out, I use the expression "*the* white rooster." But since a point of doubt has been raised as to whether one or more white cocks were employed, and since Castle claims that I make no specific statement on this point, I would refer to the table on page 565 of the paper appearing in the *Journal of Experimental Zoology*, which is headed "weights of the chickens were as follows," in which the experiment numbers of the individuals, both male and female, used in the experiment are given, together with their weights.

In respect to the evidence of soma influence, this was observed in the offspring directly from the transplanted ovaries. Therefore, it is not open to the same doubt as in the case of more indirect or circumstantial evidence. But supposing that such offspring had been bred, and supposing the offspring resulting from this mating (grand chicks) had or had not presented characteristics indistinguishable from the offspring obtained by straight breeding or of hybrids obtained by crossing unoperated fowls of the breeds employed, such results could not affect the conclusions of foster-mother influence in the first generation. It would only show that in the particular individuals presenting feather markings indicating soma influence, that similar feather markings were or were not transmitted to their offspring, or that individuals presenting no such markings might or might not transmit evidence of soma influence to the next generation. Again, the fact that the markings in all cases were not uniform in the offspring of the first generation, in no way invalidates the results. For all exact knowledge of soma influence must of necessity spring directly from experimental results. Therefore, it can not be assumed that all such offspring must present similar characters either to be acceptable as evidence that an engrafted ovary may preserve its reproductive function, or that such offspring may be influenced by the somatic tissues of the host. That is to say, it is not permissible to assume that all of such offspring would be influenced in the same direction or to the same degree. Nor can it be assumed that evidence of soma influence can be demonstrated in other combinations of fowls, much less in different species of animals.

Seemingly a lack of insight into the underlying physiological principles in such experimentation has led Castle and his collaborator into a misunderstanding, and therefore into stating their belief that my interpretation of the results, and my criticism of a statement of theirs regarding evidence of soma influence,[4] was due to a failure to grasp fully the laws of inheritance of the character which I used as a criterion. But this is more of a personal matter and therefore of no general interest.

These writers call attention to the fact that Davenport attempted to repeat my experiments on fowls, with the result that in every case spaying was incomplete, and the young from such operated hens showed no influence of the introduced graft. This is far from being an argument against the acceptance of my conclusions, as all that it shows from his interpretation is that the ovaries were incompletely removed in his experiments. But as a matter of fact, his experiments and results, while meagerly reported,[5] such as they are, might as well lead to the conclusion that he obtained very strong evidence of soma influence. That is, the chicks so closely re-

[4] "Guinea-pig Graft-hybrids," SCIENCE, N. S., 1909, XXX., 724.

[5] Davenport, "Inheritance of Plumage Color in Poultry," *Proceedings of the Society for Experimental Biology and Medicine*, 1910, VII., 168.

sembled the foster mother that he was led to ascribe the result to original ovarian tissue of the foster mother This assumption was based upon another assumption, namely, that chicks from the engrafted ovaries would preserve the characters of the fowl from which the ovaries were obtained The fallacy of this assumption has been pointed out above

Davenport did not use standard varieties of fowls, so far as I am able to determine from his statements This is unfortunate, as it is obviously impossible to discuss his findings from the standpoint of relationship of donor to host For example, I have shown that engrafted ovaries in fowls do not succeed if the stock is too distantly related

Davenport states that my results justify the opposite conclusions to those which I have drawn, but since he does not give any reasons nor present any evidence for such a conclusion, it carries no weight other than as a personal opinion

Castle and Phillips ask that my experiments be repeated before they accept my interpretation of the results In reply, I ask why they did not employ fowls (chickens) in order to confirm or discredit my experiments I may say that my first series of fowls, operated on in the summer of 1904, were all lost through lack of proper facilities The next series, operated on in 1906, were given my undivided attention and furnished the material for my papers. A larger series operated on the following year with the view of extending the observations and investigating new fields opened up by the successful series, were not productive of results in the direction of permitting the study of offspring from engrafted ovaries, but furnished considerable information along other lines which is in part presented in my later papers. Successful breeding of fowls, as every one knows, demands the fulfillment of certain requirements in the way of quarters, and facilities for hatching and raising the chicks, and intelligent attention. As to the first two of these requirements, the third series of experiments clearly proves that the quarters and facilities at my disposal, though after a manner adequate for eight fowls, the number composing the second series of experiments, were not adequate for five times this number, the approximate number that were included in the third series. Also, it was not possible for me to give as much time to the third series as to the second Immediately following this, I made application to the officers of one of the endowed research funds for support in prosecuting the investigation on a much larger scale, which included the employment of a number of species of animals But for perfectly good reasons the request was denied Since that time new experiments have been continuously in progress, but they have been designed with a view of keeping within the limits of my facilities

I do not propose to enter into a discussion of Castle and Phillips's results in this place, save to challenge their assertion that theirs is the first critical case of successful ovarian transplantation from the standpoint discussed above, on record This statement I make in view of the fundamental considerations also above stated, as well as from an examination of their protocols For example, they used mongrel stock Therefore, any evidence furnished by the character of the offspring would be of doubtful value This is true particularly as regards soma influence, and as crossbreeding was not employed, any evidence of soma influence in the offspring would have been obscured by the character of the male parent

Also it is not proven that the offspring may not have come from ovarian tissue of the host left in site after operation Indeed, an interpretation of their results from the numerical standpoint, a criterion employed by them in interpreting their results from the Mendelian standpoint, it would be as fair to conclude that in all of their pigs that became pregnant no post-mortem findings are given. And after operation that this was due to incomplete removal of ovarian tissue For they state that of the five animals in this group, the results in three were due to ovarian tissues generated from the host. Of the two animals left in the successful group, for one

denying soma influence, the results in this case might as well lead to the conclusion that the offspring were from ovarian tissue of the mother, as from the engrafted ovarian tissue. Also in the remaining animal, from the description given of the post-mortem findings it is impossible to conclude that the mother's ovarian tissue was completely removed on both sides. This objection the authors endeavor to surmount by stating that the mass of ovarian tissue found at the site from which the right ovary was removed, was apparently strongly encapsulated, so that no ovum could be discharged even if it came to maturity. Such a conclusion is of course incompatible with the evidence, for few experienced pathologists, from the evidence presented, would care to make such a definite statement as to the retention of liberated ova.

Similarly, their statements regarding the regeneration of ovarian tissue are too absolute. For example, in certain cases where both ovaries were removed and ovaries from another animal engrafted in the neighborhood, as to the horn of the uterus, the absence of ovarian tissue at the site of implantation, and the presence of ovarian tissue at the site of removal of the animal's own ovaries is not proof that the former degenerated, and the latter regenerated. For it is possible that the implanted ovaries might have come in contact with the raw surface left after removal of the original ovaries, and become attached thereto. And since the engrafted ovaries were secured in place by means of exceedingly fine strands of unraveled silk, it is by no means certain that they could not have broken away from their moorings, owing to a cutting out of the tissues or a slipping of the knots, or even a breaking of the thread, though the latter accident would probably be less liable to occur.

These are merely some points that it is unsafe to leave out of account in concluding that such experiments are critical in the absolute sense, and I wish to say that I do not urge them as invalidating their results. In fact I consider that they have added at least one more confirmatory observation upon the reproductive functioning of transplantated ovaries, probably two, and possibly five. For the evidence does not absolutely rule out the animals which they have placed in the group in which they think regeneration of the ovarian tissue occurred. But it should not be forgotten that conclusions based upon indirect evidence, though appearing absolute, are never wholly free from at least a shadow of doubt. To accept this statement, it is only necessary to trace almost any biological subject developed from indirect experimentation a little way back into the literature. Indeed, teachings based upon such conclusions have passed without question through generations, to be later overthrown. And since the element of indirectness has not been eliminated in the experimental investigation of ovarian transplantation, I have stated that my results *seem* to lead to certain conclusions. And the same applies to Castle and Phillips's results as regards functioning of engrafted ovaries.

As to their interpretation of the results from the Mendelian standpoint, the nature of some objections to their conclusions has been discussed above. In addition, I would say that it is unfortunate that they did not preserve the individuals furnishing an ovary for engrafting, leaving the other ovary in place and then breeding this female to the same male used upon the female carrying the engrafted ovary. From their paper it would seem that they look chiefly to the second generation for evidence of soma influence, the index for detecting such influence being based upon the assumption that such influence would show in the second generation. The fallacy of this assumption has also been considered above.

In conclusion, I desire to say that the continuation and extension of these experiments is of the greatest interest and importance, and I hope that Professor Castle and his pupil may see their way clear to continuing them on a larger scale, using purer varieties of animals, including fowls of not too distantly related varieties.

PHYSIOLOGICAL LABORATORY,
UNIVERSITY OF PITTSBURGH

SCIENTIFIC BOOKS

Electric Motors By H. M. HOBART London, Whitaker & Co. 1910.

The name of Hobart is so well known to designing engineers in the electrical engineering field that any work from his pen needs no introduction to members of that profession. The volume under consideration being the second edition of his "Electric Motors" of 1904 is not altogether new to the electrical engineering fraternity, but there has been a considerable revision and modernization of the subject and an increase in the size of the book The large amount of data included has also been revised to correspond to recent practise

The scope of the book includes the electrical design, predetermination of characteristics, testing, operation and methods of special application of practically all types of motors now in commercial use, including the interpole D.C. motor and the single-phase series and repulsion A.C motors

Mr. Hobart's method of treatment is largely empirical and practical and each procedure is premised by copious data taken from tests

It assumes a knowledge of the fundamental principles and familiarity with design. Thus it will serve better as a reference book for engineers and instructors than as a text-book for the student in technical schools

No general method is given for the preliminary selection of dimensions for a design, but the reader is left to consult the data given. This is a common custom among designing engineers who, from their long experience and memory, can guess at the right proportions the first time, whereas the general practitioner or student needs some criterion for his selection. Few books on design lead up to the preliminary choice of design and dimensions by a discussion of those fundamental conditions which bear upon these proportions; such as allowable peripheral speed, allowable ampere conductors per inch or ampere stream on the armature and reasonable magnetic densities.

The book contains a very valuable compilation of data on various designs, the product of several different European manufacturers. This will make it a useful reference book for the American engineer, as it gives him information on the methods which others, having a different view-point, have used to solve those problems which he has met and probably solved in his own way But it will be regretted by the general practitioner and the novice in designing, that American practise is not described. It is needless to say that designs which are very successful abroad could not be marketed here owing to the different conditions, particularly with reference to the cost of labor.

The treatment of the interpole motor, while very good, is not as extensive as a good many engineers would desire. There is need of a carefully systematized work of authority on this subject in English, something comparable to Arnold's work in German to which most designing engineers in direct-current as well as alternating-current work are obliged to refer more or less frequently.

The chapters on the Design of Induction Motors are very complete, and by means of the data included would enable one already familiar with the principles to produce very satisfactory designs, but there are certain features lacking and certain methods of treatment which would make it difficult for a person not in the habit of practising design to understand the subject Thus the subject of the leakage reactance or inductance is treated almost altogether as a function of the "circle diagram" and no statement or diagram is given showing the paths of the leakage flux and the effect on the value of this leakage flux of the number and shape of the teeth.

While it is possible to take into account this leakage reactance in the calculation of the characteristics of the machine by means of the circle diagram by referring to data given, it is nevertheless very valuable to thoroughly appreciate during the actual process of design, exactly how much each particular feature of the design contributes to this quantity. This can only be determined by actually deriving the leakage path from the shape of the punchings. Incidentally, the effect of fractional pitch on the leakage reactance is

not very clearly brought out Yet fractional pitch is very generally used in motors of American manufacture.

The chapters on the Design of Small Motors for Manufacture in Large Quantities and on Cost and Weight Coefficients are of undoubted value in concentrating attention on the factors which govern the expense, although the actual values being based on foreign practise would not be of great value to an American engineer

In a book on design as comprehensive as this it seems a pity that some space is not devoted to the mechanical design It is to be regretted that designers of the electrical features of apparatus are so dependent on the mechanical engineer to put their designs and ideas into execution.

Considerable space is given to the single-phase motor both of the induction, series and repulsion types, with the addition of very good introduction stating the logical limitations of the single-phase system

The author and publishers should be congratulated on the excellent work shown in the cuts and curves which contribute considerably to the value of the data included in the book. This is really very extensive and alone would make the book of great value to the designing engineer as a book of reference

WALTER I SLICHTER

Testing of Electromagnetic Machinery By B V. SWENSON and B FRANKENFIELD New York, The Macmillan Co 1911.

This volume is devoted to the testing of alternating-current machinery and is a sequel to the book on "Direct Current Machinery," previously published by the same authors. The book contains a description of a very large number of practical experiments illustrating the phenomena of alternating-current circuits and methods of testing commercial apparatus. It is intended to be used in technical schools in connection with a laboratory course.

The general scheme and methods are based upon the work which has been carried on in the laboratory of the University of Wisconsin under the authors, and contains additions and revisions due to the experience of Professor Bryant at the University of Illinois.

As a result of this collaboration and experience the text covers the field very completely and the methods advocated are those that would be generally conceded as the best and most practical

The book is quite up to date both in its methods and in its scope, thus a treatment of the mercury arc rectifier and the split-pole converter are included, although the treatment of the latter is very brief

It may be suggested that the experiments are resolved into too elementary and simple divisions and that a more efficient use of the student's time would be obtained by combining several of the experiments into one operation. There are 127 experiments listed, very few of which could be omitted from a good course, but these 127 could be logically grouped to cover the same ground in fewer operations.

For the theoretical basis and explanation of each experiment, the student is referred to a very large number of references in each experiment The number of these references will in itself tend to discourage the average student to give any of them proper attention. It would be of more benefit to the student if a simple and concise development of the theory were included in the text with each experiment. However, for instructors in charge of courses these references so systematically arranged will be of great use.

WALTER I. SLICHTER

Economic Geology, with Special Reference to the United States. By HEINRICH RIES, Ph.D. Third edition. New York, The Macmillan Co. 1910. Pp. xxxiv + 589, pls. LVI., figs. 237. $3.50.

The importance of geology in its relations with mineral resources was recognized nearly a century ago in the establishment of official surveys. Still earlier in the European schools of mines the formation and classification of ore deposits were discussed in formal courses of lectures. But the growing development of agriculture, quarrying and mining has brought the science of geology more and more into the

foreground among subjects of importance in general education, and more and more courses in the purely scientific statement of the subject are followed up by those in its applications.

The text-book before us covers the latter field. It aims to carry a student through the various useful minerals and rocks, to instruct him in their modes of occurrence, the principles governing their accumulation and the statistics of their production. The non-metallics are first discussed, beginning with coal. Then follow in order, in Part I., petroleum and related hydrocarbons, structural materials, salines, fertilizers; abrasives, various minor minerals, and finally underground water. The author has freely used maps and pictures and summarizes literature at the close of each chapter. In the matter of clays and their applications he is especially at home from long experience with this particular line of investigation.

Part II. is devoted to the metalliferous deposits. An introductory chapter on the geological principles involved and the scheme of classification to be employed leads up to a systematic description of the ores of iron, copper, lead, zinc, gold, silver and the lesser metals. Again maps are freely used and with geological sections and pictures convey excellent ideas of occurrence and distribution. Statistics add the proper sense of perspective and of relative magnitudes.

The author writes with obvious knowledge and command of his subject. Successive years of presentation to classes and the two previous editions of the work have aided in bringing it to a high grade of excellence. The publishers have cooperated with maps and illustrations, with the result that a concise and very useful manual has resulted.

J. F. KEMP

PSYCHOLOGY IN RUSSIA

AT the eighth annual meeting of experimental psychologists, held at Cornell University, April 17–19, 1911, Professor G. Tschelpanow, of the University of Moscow, described the status of psychology in Russia at the present time. He has been commissioned by his government to study psychological laboratories abroad, in order to perfect plans for the erection and equipment of a psychological laboratory building, the first and most complete of its kind—and to be established at Moscow, in the heart of Russia! This laboratory is the gift of Mr. S. I. Shtchukin, of that city, who has contributed 100,000 Rubel ($50,000) for the building and 20,000 Rubel for its equipment. He is already well known as a benefactor and protector of the modern school of painters, and has a large private museum of modern pictures which is often visited by English and French artists. The new laboratory is also endowed with a library of 3,000 volumes, worth 10,000 Rubel, presented as a memorial by the family of a young instructor of the University of Moscow, who met with an untimely death.

Professor Tschelpanow addressed the audience in German, but he kindly permitted me to translate the notes I had taken and to publish them, in spite of their sketchy, unfinished form, as I considered his remarks of general interest to scientists at large. He said in part:

"Experimental psychology in Russia is still in its beginning, although the first interest for it was aroused as much as twenty years ago. Its progress has been impeded partly by the uncertainty of political conditions, partly by the close affiliation of psychology with philology only, and not with natural sciences, and partly also by the fact that Russian universities have only collegiate rank, so that most of their advanced students still have to go to Germany for their research work.

"Among the older psychological laboratories, that at Odessa has become most widely known through the work of N. Lange. For some time he had but scanty space and only a few pieces of demonstrational apparatus at his disposal. At Kiew the laboratory consists of two rooms which contain demonstrational and other instruments. Moscow is in this respect the most fortunate place of all, because four years ago its laboratory was

started with four rooms and an initial endowment of 3,000 Rubel It now has thirty students in experimental psychology, some of whom are undertaking independent work Among the problems already attacked are the study of reaction-types, Reuther's method of recognition, work on memory-types with the Binet method improved by controlled time-exposure, and the correlation of the three psycho-physical methods in regard to estimation of spatial extent In the teaching of experimental psychology the Russian professors depend very largely upon translations of American text-books, especially those of Sanford and Titchener

"In recent years applied psychology has become very popular and influential, through the work of Netschajeff and his cooperators, who have established about fifty psychological institutes at various *gymnasiums* and secondary schools where psychological instruction has been introduced The method of making mental diagnosis has, however, reached a crucial point in Russia, inasmuch as strong opposition has set in toward a newly developed practise of outlining and analyzing mental abnormalities by reference to characteristic curves, especially when employed by comparatively inexperienced teachers Objective or physiological psychology is represented chiefly by the well-known work of Bechterew and Pawlow, while interest in theoretical psychology still predominates"

After the meeting, Professor Tschelpanow showed and explained the architect's plans for the new laboratory, which is to be a three-story building The basement will contain the heating plant, a workshop, a sound-proof room, space for animal psychology, large electric motors, and the apartments of the janitor and the mechanician On the first floor, an auditorium with a seating capacity of three to four hundred persons and a room for demonstrational apparatus are provided for; furthermore, the director's office, the library, a room for collections of mental products, and a general writing room, are to be located here. The plan of the second floor makes allowance for a small lecture-room, for offices of the assistants, and for about twelve rooms in which the introductory courses for qualitative and quantitative experiments will be conducted The third floor, finally, is to be given up entirely to research, and for this purpose it will be divided into twenty smaller rooms A special feature on this floor is a large switchboard for the distribution of electric power The building will be situated on university grounds, surrounded on all but one side by other university buildings, but removed as far as possible from public traffic From all indications it promises to be an ideal home for the pursuit of psychological investigations, and it is to be hoped that the generous gift of Mr Shtchukin will prove a fruitful example to other countries

CORNELL UNIVERSITY

THE TIME GIVEN BY UNIVERSITY STUDENTS TO STUDY AND RECITATION

IN connection with some committee work in Indiana University the writer was appointed chairman of a sub-committee to ascertain the time given by the students to their work

It is thought that a brief summary of the results might be of general interest. Blank cards were handed to the students of all classes on Monday, February 14, 1910. The students were instructed to fill in the cards for all their courses Each student was to fill out one card only, that is, if the student had an eight o'clock recitation, say, he filled out the card for all his courses If he then went to another class, nine o'clock, say, he returned his card blank.

The cards called for the department, the number of course, the number of hours credit, the number of hours spent per week by the student in recitation or laboratory, and the number of hours spent per week by the student in home or library study. The card had blank spaces so that as many as seven courses could be filled in, if necessary. The total time spent by the students per week on a course was added and then divided by the number of credit hours, thus giving the time spent by the

individual student per week per credit hour for each course

The cards were then arranged in alphabetic order From the mid term reports rolls of all the classes in the university were procured By referring to the cards the time given by the student to the particular course was marked opposite the student s name and the average time per week per credit hour was determined for each course

By summing the totals of the courses and dividing by the total number reporting the average time was determined per instructor and per department as well as the grand average for the university

Due to various causes such as absence of students or forgetfulness of the instructors reports were not obtained from all students Approximately 75 per cent of the students reported About nine hundred cards were returned to the committee A few of these were thrown out because they were not filled out properly The cards showed that for a total of 4 438 registrations 13 951 7 hours per week spent or an average of 3 14 hours per week per credit hours (15 credit hours is regular work at Indiana University) That is the average student spends 3 14 hours on each recitation If the course is one in which no laboratory is required he spends 1 hour in the class and 2 14 hours in preparation If the course is a laboratory course requiring two hour two-and-a-half hour or three-hour periods the student spends 1.14 hour 0 64 hour or 0 14 hour respectively in outside preparation

TABLE I

By Departments

Department	Enrollment	No Reported	Hours per Week per Credit Hour
—	60	50	4.10 hours (highest)
—	304	255	[illegible]
—	5	4	[illegible]74
—	244	18[illegible]	3.58
—	956	65[illegible]	3.55
—	93	78	2.63
—	68	51	2 68
—	107	80	2.52
—	71	50	2.54 (lowest)

In order to give an idea of the range I have arranged three tables—Table I by departments Table II by instructors and Table III by courses giving the enrollment the number of students reporting and the number of hours per week per credit hour starting at the highest and ending with the lowest

TABLE II

By Instructors

Instructor	Enrol ment	No Reported	Hours per Week per Credit Hour
—	38	22	4 25 hours (highest)
	109	95	4 01
	54	50	3 97
—	41	31	2 38
—	69	51	2 17
—	30	19	2 14 (lowest)

TABLE III

By Courses

Course	Enrollment	No Reported	Hours per Week per Credit Hour
—	11	9	5 38 hours (highest)
—	31	25	5 07
—	15	11	4 38
—	4	3	4 30
	10	9	1 92
—	4	3	1 66
—	24	19	1 25 (lowest)

It is true that the figures do not represent the facts in all cases To the lazy student who has knowingly slighted his work the temptation would be great to increase the time of study On the other hand the plodding student would tend to underestimate his time In certain cases the student may have heard that the proper time for the course was about so much Under those conditions the average student will consciously or unconsciously make his figures correspond to the standard However, the averages of large numbers may be taken to be near the true value In any case, the figures are not without interest

SPECIAL ARTICLES

BIOLOGICAL CONCLUSIONS DRAWN FROM THE STUDY OF THE TITANOTHERES[1]

THE chief object of this communication is to point out a possible harmony between the "continuity" and "discontinuity" theories of the phenomena of development

The titanotheres, as an extinct family of mammals extending from the summit of the Lower Eocene to the summit of Lower Oligocene times, offer an exceptional opportunity for the solution of the two chief modern questions of evolution first, the mode of transformation of existing characters, second, the mode of origin of new characters The material available is now the most complete of any extinct family of mammals, embracing several nearly continuous series which branch out into a large number of phyla, some of which may be carried through all the phases of transformation The investigation has been carried on with the aid of Dr W K Gregory, and is marked by the introduction of a very exact system of measurements, whereby the various kinds of transformation may be studied in numerical terms This exhaustive research appears to have a significant bearing upon the diverse theories of transformation entertained by the two modern schools of thought, the zoological and botanical, and the paleontological

From the time of Waagen in 1869, who introduced the term "mutation" for the *stages* of the continuous development of certain inconspicuous but genetically important characters in Ammonites, the idea of continuity has become the established law among paleontologists. Neumayr added the conception of "*Mutationsrichtung,*" that is, of trend or direction of development The researches of Hyatt and Beecher were directed rather to the phenomena of recapitulation than specifically to the phenomenon observed by Waagen. Their writings, however, bring volumes of testimony to the law of continuity of development. This law has been established among vertebrates as well as invertebrates The nature of the evidence presented to the paleontologist is entirely different from that presented to the zoologist, as an observer the former is practically immortal, that is, his range of observation, where it is possible to assemble continuous series of organisms, extends over enormous periods of time in contrast to the fleeting and essentially mortal glimpses which the botanist and zoologist may obtain of the fundamental processes of transformation

Over against the idea of continuity, of definite development, and of certain trends of evolution, there have been developed among the students of living animals and plants (Bateson, de Vries and others) the notion of discontinuity and of order or orderly development produced only by selection To this discontinuity de Vries has unfortunately applied the same term "mutation" which was introduced into biological literature by Waagen with entirely different significance, the name *saltation* should be attached to the de Vries hypothesis, until this is done we must speak of "mutations of Waagen" and "mutations of de Vries" The discontinuity conception has been strengthened rather than weakened by the wonderful revelations of Mendelian heredity, including the doctrine of unit characters and of "alternate inheritance"

The only tenet which the "continuous" and "discontinuous" schools of thought hold in common, or rather have reached in common, is that germinal evolution is the chief phenomenon upon which our attention must be concentrated. In the present communication the phenomena resulting from somatic changes or ontogeny, from environment, and from selection may be left out of consideration, and we may direct our thought solely and exclusively upon germinal evolution as it is displayed in the origin of new characters and in the transformation of existing characters in the titanotheres.

In all the sequence of the titanotheres only four kinds of change are observed: (1) *Increase of size.* This happens to be an almost

[1] Abstract of paper presented at the meeting of the National Academy of Sciences, Washington, April 19, 1911. Based upon the author's monograph "The Titanotheres," in preparation for the U. S. Geological Survey.

universal principle in this family, although it is by no means universal among mammals nor even among the Herbivora. (2) *Loss of parts* This plays a very small part in the series of titanotheres as compared, for example, with the horses, since the chief parts lost are one element in the carpus, the trapezium and certain upper and lower incisor teeth (3) *Changes of proportion* This comprehends one of the most important and significant parts of titanothere evolution Such change it is proposed to designate as "allometric," and new parts originating in this way may be termed "allometrons" (4) Continuous definite or *adaptive origins* of new characters, which the writer has previously termed "rectigradations"

Of the above phenomena (1) increase of size and of (2) loss of parts may be left out of consideration, and attention may be directed upon the (3) *allometrons* and the (4) *rectigradations* It is found at once that their mode of appearance or the laws governing them are definite

First, as to *rectigradations*, as exemplified by new cusps upon the teeth or by newly arising horns upon the skull, we find them subject to four important principles (1) Rectigradations appear under the law of ancestral hereditary control, that is, the same rectigradations arise independently at different times in the descendants of remote common ancestors This law has already been enunciated at a previous meeting of the academy and constitutes one of the most important generalizations brought out by the study of the titanotheres. (2) Rectigradations are continuous, arising from infinitesimal and almost invisible beginnings and passing into a stage of usefulness; this principle was pointed out many years ago by the author and described as "definite variation." (3) Rectigradations from the time of their first appearance are subject to the allometric influence of surrounding parts, thus a horn arising as a rectigradation in a brachycephalic skull will assume from the beginning a rounded form; arising in a dolichocephalic skull it will assume an elongate or oval form. (4) It is probable, but has not yet been demonstrated, that rectigradations are subject to fluctuations, that is, are more or less strongly developed around an average mean

Second, the *allometrons* or changes of proportion follow partly the same and partly different laws than those pursued by the rectigradations The most fundamental difference is the following: allometrons arise independently of remote ancestral hereditary control, that is, from a mesaticephalic ancestor there may arise, on the one hand, a dolichocephalic, and, on the other hand, a brachycephalic descendant, when, however, a trend of development, a law which appears to be coincident with the "*Mutationsrichtung*" of Neumayr, is once established then a tendency toward brachycephaly or dolichocephaly, respectively, becomes increasingly manifest, in this sense allometrons resemble rectigradations The second law is that allometrons are continuous This is positively demonstrated in certain phyla, and apparently will be demonstrated in all the phyla as soon as a full series or sequence is obtained Any other theory of change of proportion but continuity is untenable in the face of the hundreds of measurements which especially demonstrate progressive brachycephaly Measurements demonstrating progressive dolichocephaly and cytocephaly, or the bending down of the facial upon the cranial region of the skull, are based on less complete series

It has been found convenient to introduce a series of cephalic indices of the ratios between breadth and length similar to the cranial indices used in anthropology Thus, breadth — length gives the cranial index of a titanothere, and the gradual transformation from mesaticephaly into brachycephaly or dolichocephaly may be expressed in exact numerical terms Every bone of the skull enters into these remarkable transformations, and every single bone has its own individual percentage of increment. The evolution of every part is differential. Thus there is no general stretching of the skull in dolichocephaly, as if it were composed of india rubber; the elongation may be confined to cer-

tain regions It has recently been found that the ancestral titanotheres are dolichocephalic, of the type known as proopic-dolichocephaly because the chief elongation is in front of the orbital region Their descendants are also dolichocephalic, but the type is opisthopic dolichocephaly, that is, the chief elongation is behind the orbital region

Similar allometric indices are also found in the limbs For example, the ratio of the length of the tibia to that of the femur is very significant and is constantly changing in adaptation to weight and to speed.

Considering the transformation of the titanotheres in comparison with that of the horses and many other lines of mammals, where successive series have been obtained, we observe again exactly similar phenomena It *appears that the law of continuity, of orderly and in a sense of predetermined transformation can now be established beyond refutation*

The question then arises whether these laws of "continuity" can be harmonized with the potent demonstration that certain new characters and certain new proportions arise as saltations or discontinuously The hypothesis which is here advanced is that continuity is the normal mode of development under natural conditions, that there are certain definite trends or tendencies, that there is in continuous series a "*Mutationsrichtung*," that by this continuous development the greater number of so-called "unit characters" have arisen, that occasionally, however, new unit characters may and do arise suddenly The hypothesis may be expressed as follows that the normal development of unit characters is a continuous progress, that under certain abnormal conditions, as of sudden change of environment, certain new unit characters may appear suddenly, that the cross-breeding of pure natural races in which unit characters have been built up by continuous processes breaks up these unit characters into a mosaic and gives rise to the larger part of the apparently saltatory or discontinuous phenomena which are being observed by the modern experimentalists.

As illustrations of this hypothesis, take as a very simple one the transformation of the head form in various human races, the development of dolichocephaly and of brachycephaly has in all probability been by continuous transformation in one direction or the other In support of continuity is the evidence adduced among the titanotheres. When dolichocephalic and brachycephalic races intermingle, the fact that dolichocephaly or brachycephaly is a unit character appears at once in the non-blending of head form subject to the law of alternate inheritance Another illustration is afforded by the results of the interbreeding of pure stocks of the horse, namely, according to the observations of Ewart, the Arab, or plateau type, the Przewalsky, or steppe type, and the draught, or forest type Each of these pure original stocks apparently acquired by gradual transformation a very large number of distinctive characters displayed in the head, in the teeth, in the backbone, in the limbs, and last but not least in the psychic activities of these three great strains which have been bred for ages among very diverse environmental conditions As soon as these three pure stocks are intermingled the fact that each is a mosaic of an enormous number of single, or unit characters becomes apparent in the mosaic type of horse which is produced, a horse showing singly or in groups various unit characters of the plateau, steppe or forest types The transformation which, for example, has built up respectively the slender cannon bones of the desert and heavy cannon bones of the forest type has been, we have every reason to believe, a continuous, or progressive, or allometric change On interbreeding, these slender or massive proportions may partly blend or may be detached as "units" from the progressively slender or massive head types to which they belong.

By far the greater number of the experiments carried on in support of the theory of discontinuity have been among hybrids, crossed strains, artificial strains, or strains subjected to unnatural changes of environment. It is important, therefore, for experimentalists to extend their work among abso-

lutely pure, natural races Wherever nature is experimenting, as discerned by the field zoologist in the observation of geographic series from east to west, and north to south, from humid into arid regions, we are repeatedly finding geographically continuous series which shade into each other in color, in skull proportion, and limb proportion, and all other characters by continuous degrees of change

HENRY FAIRFIELD OSBORN

UNDERGROUND TEMPERATURES

IT is an established fact that as the earth is penetrated below the limit of seasonal changes the temperature is invariably found to rise Observations made in deep borings, wells, tunnels and mines have been sufficiently numerous over the earth's surface to indicate that the rise of temperature with depth "can not be explained on mere local causes" The rate of temperature increase is not uniform but is found to be quite variable, not only in different localities, but frequently in the same boring This variation of heat increment is doubtless due to a number of causes,[1] such as differences in the thermal conductivity of rocks which vary in lithologic character, structure and contained water, inequalities of topography, circulation of water, chemical action, compression, etc. Whether the heat increment observed in the superficial zone continues to the center of the earth is not known, as observations are limited to only a little more than 1/4,000 of the earth's radius. Some investigators regard it as more probable that the rise of temperature diminishes below the superficial zone.

The conducting power of rocks was first accurately measured by Forbes[2] and later by others. Forbes found that trap rock was the poorest conductor and solid sandstone the best. Sir Archibald Geikie[3] says, "the lighter and more porous rocks offer the greatest resistance to the passage of heat, while the more dense and crystalline offer the least resistance." The British Association Committee on Thermal Conductivities of Rocks[4] expressed the resistance of quartz by the number 114, basalt by 273, and cannel coal by 1,538 The same authority[5] records that heat travels four times as fast in foliated rocks, such as slate and schist, in the direction of cleavage than across it. It has been shown also that thermal resistance is lowered by the presence of interstitial water

The subject of underground temperature attracted attention as early as nearly two centuries ago, when observations were made in the mines of Alsace by Gensanne in 1740, who found an increase of 1° F in 50 feet Among some of the earlier observers may be mentioned Saussure, Humboldt, Daubuisson, de Tebra, Forbes and Fox, Henwood, Cordier, De la Rive and Marcet, Phillips and others

From 1868 onwards the British Association Reports contain valuable contributions by the committee on underground temperatures, and a summary is published in the volume for the year 1882. In 1886 Professor Prestwich's[6] valuable contribution on the subject of underground temperatures appeared, in which he collated all available data up to that time This paper was later revised and published in his "Collected Papers on some Controverted Questions of Geology," 1895, pp 166–279 Observations have been made and data bearing on this subject have been contributed at intervals to the literature from 1886 to the present time, with the conclusion that while there is an undoubted increase in temperature downward, the rate is more variable than was at first supposed

Professor Prestwich gave the number of different localities and mines where observations were recorded as 248, and the number of stations 530. He found, with but few excep-

[6] *Proc. Roy. Soc. of London*, 1886, Vol. XLI, pp. 1–[illegible]

tions, that the earlier observations were inferior and of little value for purposes of accuracy, due chiefly, he says, to the imperfection of instruments and methods of experimentation. Because of the careful digest by Professor Prestwich of the voluminous data bearing on this subject, I regard it of sufficient interest to note briefly the following extracts from this valuable paper The author classified the recorded results on underground temperatures into—(1) metallic mines, (2) coal mines, (3) wells and wet borings and (4) tunnels. The increase of temperature was found to be: (1) metallic mines, from 1° F. in 47 feet to 1° F in 126 feet, (2) coal mines, from 1° F. in 45 feet to 1° F in 79 feet, (3) wells and borings, from 1° F. in 41 feet to 1° F in 130 feet; (4) tunnels—Mont Cenis, 1° F for 79 feet; St. Gothard, 1° F for 84 feet. The mean of these results gave 1° F in 64 feet Subsequent corrected readings in the two tunnels reduced the mean to 1° F in 60 feet

Professor Prestwich regarded the differences in results obtained in mines, wells, etc, indicated by an examination of the tables, to be attributed to the fact that the geological conditions were unlike, and the disturbing causes of a different order The main disturbing causes in the different groups of openings made are stated and discussed In coal mines they are stated as (1) loss of heat through exposed surfaces, (2) effects of ventilation, (3) other causes, such as crushing of rock, escape of gas, and effects of irregularities of surface (pp. 9–21). There are local variations according to structure, percolation of water, etc. From the reliable cases, the mean increase for coal mines was found to be 1° F in 50 feet.

In metalliferous mines the main causes affecting thermal conditions are given as (1) ventilation, (2) percolation of water, (3) hot springs, due (a) to chemical decomposition and (b) to water coming from great depths[7] (pp 25–34). The mean thermometric gradient was found to be 1° F. in 44 feet in rock, and 1° F in 42.4 feet in springs, with an average for the two of 1° F. in 43.2 feet.

In wells and borings the main disturbing causes are regarded as (1) pressure on the instruments, and (2) convection currents. The mean thermometric gradient in this group of openings was found to be for non-flowing wells 1° F in 51.2[8] feet, in flowing wells 1° F in 49.1[8] feet, with an average for the two of 1° F in 50[8] feet

A paper entitled "Rock Temperatures on the Rand and Elsewhere," by E M. Weston,[9] published in a recent number of the *South African Mining Journal* is of interest The tables which follow below are taken from this paper

Rock Temperatures in Depth on Witwatersrand Mines

Rock Temperature at	
1,000 feet	68 75° F
2,000 feet	73 53
3,000 feet	78 35
4,000 feet	83 15
5,000 feet	87 95
6,000 feet	92 75
7,000 feet	97 55
8,000 feet	102 35

General rate of increase, 1° F for 250 feet.

In the Lake Superior copper district, the Tamarack shaft is reported to have reached a depth of 6,070 feet, and the Red Jacket shaft a depth of 5,315 feet. The rate of increase in temperature is given as 1° F. for 209 feet. In a note published by Professor Alexander Agassiz in 1895, the greatest depth reached in the Calumet shaft was 4,712 feet, which showed an average increase in temperature of 1° F. for 223.7 feet.[10] Two bore holes are reported put down in Silesia to depths of 6,500

[7] In his revised paper, Professor Prestwich adds "the working operations" to the list of causes affecting thermal conditions in metalliferous mines. "Collected Papers on some Controverted Questions of Geology," 1895, p. 179.

[8] 52.2, 50 6 and 51.4 feet, respectively, in the revised paper. *Ibid.*, 1895, pp. 226 and 231.

[9] *South African Mining Journal*, November 12, 1910, p 417.

[10] "On Underground Temperatures at Great Depths," *Am. Jour. Sci.*, 1895, Vol. L., pp. 503–504.

feet and 7,847 feet, with bottom temperatures of 158° F. and 181° F., respectively.

Rock Temperatures in Brazil Mines

(St. John Del Rey Mine, Minas Geraes)

Rock Temperature at	
324 feet	70.0° F.
624 feet	71.0
924 feet	74.0
2,073 feet	78.0
2,824 feet	84.5[11]
3,724 feet	88.0
4,024 feet	95.0

Vertical depths of more than 4,500 feet are reported reached at Bendigo, Victoria, Australia, with a rock temperature of 110° F. at 4,000 feet. At the Adalbert mine in Bohemia the greatest depth is stated to be 3,600 feet, with a rock temperature between 3,500 and 3,600 feet of 113° F.

Rock Temperatures in Kalgoorlie Mines

Rock Temperature at	
1,400 feet	84° F.
1,700 feet	83
2,000 feet	83
2,300 feet	84

Data bearing on artesian-well temperatures in the Dakotas were tabulated and discussed by Darton[12] in 1898, which indicated very high and variable temperatures and for which no satisfactory explanation was offered. Records from 49 localities were given in which the depth of well varied from 432 feet to 2,500 feet, and the rate of temperature increase ranged from 1° F. in 17.5 feet to 1° F. in 45 feet, with an average of 1° F. in 35.4 feet. At the Pittsburgh meeting of the Geological Society of America, December, 1910, Mr. Darton read a paper entitled "A List of Underground Temperatures in the United States" in which he said: "The rate of temperature increase has been found to be very variable, but in places there is a marked relation to geologic features."[13]

The records of the Committee on Underground Temperatures, of the British Association for the Advancement of Science, show a range of 1° F. in less than 20 feet to 1° F. in 130 feet, with an average of 1° F. in 64 feet. Professor Prestwich concluded that the average increase in temperature was 1° F. in 47.5 feet (p. 55). Lord Kelvin assumed the rate of increase to be 1° F. in 51 feet. A lower rate of increase is indicated in more recent deep borings that have been carefully measured. From the data given above, quoted from the article by Weston on increase of temperature with depth in metalliferous mines, the general rate of increase in thermometric gradient for the different localities is in the Witwatersrand mines from 1,000 feet to 8,000 feet, 1° F. for each 250 feet in depth, in the copper mines of the Lake Superior district, 1° F. for each 209 feet, in the St. John Del Rey mine, Brazil, 1° F. for each 156 feet, approximately, and in the Kalgoorlie mines, Australia, practically no variation in temperature is indicated between the depths of 1,400 feet and 2,300 feet.

Professors Chamberlin and Salisbury give the following list of records:[14]

Locality	Depth in feet	Rise of 1° F
Sperenberg bore (Germany)	3,492	in 51.5 feet
Schladeback bore (Germany)	5,630	67.1
Cremorne bore (N. S. Wales)	2,929	80
Paruschowitz bore (Upper Silesia)	6,408	62.2
Wheeling well (W. Va.)	4,462	74.1
St. Gothard tunnel (Italy Switzerland)	5,578	82
Mt. Cenis tunnel (France Italy)	5,280	79
Tamarack mine (N. Mich.)	4,450	100
Calumet and Hecla mine (N. Mich.)	4,939	103
Ditto, between 3,324 feet and	4,837	93.4

In commenting on these records the authors say:

[11] Equals sea level.

[12] Darton, N. H., "Geothermal Data from Deep Artesian Wells in the Dakotas," *Am. Jour. Sci.*, 1898, Vol. V. (N. S.), pp. 161–168.

[13] "Preliminary List of Papers, 23d Winter Meeting, Geol. Soc. America, Pittsburgh, Pa.," December, 1910, p. 2.

[14] "Geology," Vol. I., Geologic Processes and their Results, 1904, p. 543.

It is to be noted that even these selected records vary a hundred per cent Very notable variations are found in the same mine or well, and often much difference is found in adjacent records, especially those of artesian wells Some of these are explainable, but the full meaning of other variations is yet to be found[19]

In conclusion, it may be stated that from recent figures bearing on this subject, no general law is observed in the increase of rock temperature with depth, and in general the increment of heat is lower and more variable than indicated by the earlier observers

THE SCALES OF THE DIPNOAN FISHES

I AM greatly indebted to Dr G. A Boulenger for scales of the few living members of the very interesting and remarkable subclass known as Dipnoi or Dipneusti. The result of their examination is quite surprising to me, and has, I think, an important bearing on their relationship with other fishes

Neoceratodus forsteri, from Queensland, has very large oblong scales, one before me being 55 mm long and 34 mm broad, 20 mm or less of the length being exposed in the living fish In general appearance, the scales are not unlike those of *Heterotis*, except for size The broad nuclear field, far apicad of the middle, is rugose, the circuli (fibrillæ) are all very fine, and both basal and apical are longitudinal; the basal fibrillæ are moniliform (minutely tuberculate), and in the lateral fields the whole surface is minutely rather irregularly tuberculate. Thus in its longitudinal fibrillæ *Neoceratodus* agrees with *Amia* and *Albula;* in having the fibrillæ tuberculate or beaded it agrees with *Albula* and the Osteoglossidæ. At first sight it seems that there are no radii in *Neoceratodus*, but closer inspection shows a complete system of fine radial reticulations, especially well developed in the lateral areas, where it accords perfectly with the network-pattern of the Osteoglossida! This exceedingly characteristic feature is now known, therefore, in the Dipnoans, the Osteoglossids and the Mormyrids[1]

Having determined these facts, I turned with eagerness to the material of *Lepidosiren* and *Protopterus* In these fishes the scales are completely enclosed in the skin, but are, nevertheless, quite large (fully 8 mm. diameter in *Protopterus*), and shaped much as in *Osteoglossum* Both have a strong radial network, while the circuli are reduced to innumerable fine tubercles or coarse granulations, approaching the condition of the lateral areas in *Neoceratodus* *Protopterus annectens* from Africa (Gambia) and *Lepidosiren paradoxa* from Brazil have scales of entirely the same type, but in the *Protopterus* the network is more regular and more obviously similar to that of the Osteoglossids In both the fibrillar granulations tend to run in lines near the margin, but this is rather more marked in *Lepidosiren,* the indications are in each case of longitudinal (not circular) fibrillæ The general results may be thrown in the form of a table, thus:

(*A*) Basal fibrillæ longitudinal
- (*a*) Fibrillæ moniliform or tuberculate.
  - (1) With radial network . . . Dipneusti.
  - (2) Without radial network . . . *Albula* and *Dixonina*.
- (*b*) Fibrillæ not tuberculate, no radial network . . . *Amia calva, A scutata*.

(*B*) Basal fibrillæ circular (normal circuli); radial network present
- (*a*) Fibrillæ tuberculate . . . Osteoglossidæ.
- (*b*) Fibrillæ not tuberculate . . . Mormyridæ.

It is also to be remarked that *Gymnarchus* (Mormyridæ), *Heterotis* (Osteoglossidæ), *Lepidosiren* and *Protopterus* all have larvæ with external gills.

Dr Boulenger has very kindly sent me the scales of the Osteoglossids *Scleropages formosus* from Borneo, *Scleropages leichardti* from Queensland and *Osteoglossum bicirrosum* from Cadajos, Brazil. They are practically circular (*S. leichardti* rather broader), and all have exactly the same structure, notwithstanding the wide geographical separation The scales of *Heterotis niloticus* differ

[1] For the last, see Smiths. Misc. Coll., Vol. 56, No 3, p 2.

in being oval *Pantodon* (fam Pantodontidæ) also has strongly tuberculate basal circuli T. D. A. Cockerell

SOCIETIES AND ACADEMIES

THE NEW YORK ACADEMY OF SCIENCES
SECTION OF BIOLOGY

The regular monthly meeting of the Section of Biology held at the American Museum of Natural History, March 13, 1911, was devoted to a public lecture by Dr George A. Soper, president of the Metropolitan Sewerage Commission, on the "Scientific Aspects of the Work of the Metropolitan Sewerage Commission"

In connection with the investigations of the commission upon the pollution of the waters of New York harbor from various sources, a great amount of scientific work has been done by Dr Soper and his assistants The most interesting features of this work and its results were dwelt upon in popular manner by the lecturer

At the regular monthly meeting of the section held at the American Museum of Natural History, April 10, 1911, Chairman Frederic A Lucas presiding, the following papers were read

A New and Peculiar Porpoise from Japan Roy C Andrews

The speaker exhibited photographs and parts of the skeleton of a new porpoise secured in the summer of 1910, in Rikuzen province, Japan This specimen is allied to *Phocæna dalli* True, and with that species forms a distinct group of *Phocæna*-like porpoises which deserves generic rank This group resembles *Phocæna* externally, but has white side and ventral areas sharply defined from the black of the upper parts, a falcate dorsal fin, and vertebræ numbering 95 or more The type of the new genus to which *Phocæna dalli* was referred is the specimen which was secured in Japan, and has been formally described in a *Bulletin* of the American Museum of Natural History, now in press

The Japanese porpoise presents characters, both externally and in the skeleton, which distinguish it from all other members of the entire family. The caudal peduncle shows a strongly marked "hump," and ventrally a prominent concavity which gives the posterior portion of the body a most extraordinary appearance The neural spines of the entire vertebral series are extremely long and slender, reaching a height much greater than in any other known member of the Delphinidæ The transverse processes are also very long and rod like The number of vertebræ is 95, approaching closely *P. dalli*, which has 97 The scapula is unlike that of any other member of the family in that its height almost equals its greatest breadth, and it is in general shape somewhat like that of a Baleen whale

The specimen is, on the whole, one of the most remarkable members of the Delphinidæ that have thus far been discovered

Observations on Birds and Fishes made on an Expedition to Florida Waters J T Nichols

This paper concerned itself with a trip through Florida waters on Mr Alessandro Fabbri's yacht *Tekla* in the interests of the American Museum's department of fishes

Attention was called to the abundance of the white ibis and Louisiana heron, contrasted with the scarcity of aigrette bearing herons After a brief mention of the work and the results obtained, the balance of fish life in a fresh water outlet of the everglades was compared with the balance of fish life in the salt water as at Key West

In the former situations gar pikes (*Lepisosteus*) were abundant, as were various Centrarchids (among them the large mouthed bass and blue gill sunfish) which darted in and out through the little channels among the weed, but which did not drive head first through the masses of weed as did the leathery skinned gars, and only made quick sallies into the shallower and less open waters, where various species of Pœciliids, especially *Gambusia*, and *Fundulus goodei* were tremendously abundant The surprising freedom from mosquitoes was mentioned and it was pointed out how the existing balance of fish life was favorable to a great abundance of *Gambusia*, etc, which might be expected to prey on mosquito larvæ The Centrarchids would be likely to hold in check a fish like the banded pickerel, which would have followed these small fishes into the shallows where the Centrarchids did not follow them, and perhaps materially reduced their numbers The situation here where the large primitive gar, the spiny rayed modern Centrarchids and the abundant intermediate Pœciliids made up the bulk of the fish population, was compared with the more complicated marine situation where large selachians and spiny rayed basses, snappers, grunts, wrasses, scorpion fishes, etc., and schooling herrings and anchovies of various sorts in a way constituted homologous classes.

PROFITABLE AND FRUITLESS LINES OF ENDEAVOR IN PUBLIC HEALTH WORK[1]

IT is in accord with the spirit of this Congress to consider public health questions either from the point of view of things already accomplished by the application of the scientific method or from that of things to be done I have chosen to speak especially of "the saving of waste and increase of efficiency" still to be expected when public health problems are approached in a scientific spirit

It is well recognized to-day by many experts that while some of the ordinary activities of municipal health departments are of unquestionable value in conserving the health of a community, others are relatively ineffective or possibly worthless. One well-known writer[2] has thus expressed himself on this point

> I boldly assert that if every case of communicable disease were promptly reported to the proper local board of health and as promptly placed under effective sanitary control and so kept until danger of infection had passed, all the other present day activities of boards of health, whether local, state or national, with the exception of those directed against certain causes of infant mortality, and the possible further exception of some food and drug inspection, might be dropped with no appreciable effect upon the general health or mortality of any of our states or most of our cities

In all fairness it must be admitted that a part of the energy of almost every municipal health department in this country

[1] Paper presented before the Congress of Technology, Boston, April 10, 1911, to commemorate the fiftieth anniversary of the granting of the charter to the Massachusetts Institute of Technology.

[2] M N. Baker, chairman Committee on Municipal Health and Sanitation, National Municipal League.

is devoted to combating imaginary dangers or applied to tasks that have only a remote bearing on the public health.

This condition, as a rule, is not due to ignorance on the part of health officials, but to the pressure of public opinion. Such pressure is often exerted directly through legal ordinances passed by uninformed legislative bodies, but sometimes also through agitation by mistaken enthusiasts or through other channels of public opinion. Back of the whole situation is the existence in the public mind of wrong or antiquated conceptions of disease and the causes of disease. It was unfortunate in many respects for the cause of public health that much of the popular interest in health matters was evoked before the germ theory of disease and its corollaries became fully developed. As the result of premature generalization the public has warmly espoused a number of wrong conceptions of disease and of ways of preventing disease. To be specific, two instances of this confusion are found in the demand for garbage disposal and plumbing inspection.

Sanitarians do not admit that even a grossly improper method of garbage disposal can have much to do with the spread of disease in a sewered city or that diphtheria or typhoid fever or any other disease is properly attributable to the entrance of sewer air into dwelling houses. So firmly embedded in public belief, however, is the connection of piles of decaying garbage with outbreaks of infectious disease, and of "defective plumbing" with all sorts of maladies that to the average citizen "garbage disposal" and "plumbing inspection" bulk large as the chief if not the only activities of a municipal health department.

In the light of our present knowledge we may well ask what are the actual dangers to health from these two sources? It is now well known to bacteriologists that disease germs do not "breed" in garbage heaps, but that on the contrary if added from outside they speedily die off. The offensive odors of decomposition may be unpleasant and undesirable, there is no evidence that they produce disease or dispose to disease. On the other hand, it may be argued that the existence of heaps of decomposing organic matter tends to maintain or create general habits of uncleanliness which themselves are detrimental in a roundabout way to the health of a community. And again it is known that the house-fly may breed in garbage piles, particularly if horse manure is present, and that under certain conditions this noxious insect may become the bearer of disease germs to food. But when the worst is said it must be admitted that the known danger to health from garbage piles and "dumps" is relatively insignificant compared with the danger from other well-known but less popularly feared sources. Disease does not originate in garbage piles, however offensive they may be, the house-fly, however disgusting and annoying its habits, suffers from no disease transmissible to man, and does not convey disease unless it has access to material in which disease germs are present. The truth is that garbage disposal in large cities is more a matter of municipal housekeeping than of public health, proper methods of garbage collection and destruction must be urged rather from economic and esthetic considerations than on hygienic grounds. There are of course certain features in the handling of refuse and waste that need hygienic control, just as there are in street cleaning, but the problem is essentially not one of public health. At present in some cities the department of health is burdened with the task of caring for the city waste and its success or failure as a conservator of the

public health is too often measured by the frequency with which coal ashes are scattered in alleys or the length of time that decaying vegetable matter remains in tin cans in hot weather. In some cases the larger part of the annual health department appropriation must be expended for garbage collection and disposal, leaving only a pitifully small residue for other needs. To mention a single instance, the collection and conservation of garbage and ashes cost the Minneapolis Health Department in 1909 about $57,000, leaving approximately $43,000 for all the other activities of a health department serving a city of over 300,000 inhabitants.

One thing should be clearly understood by municipal authorities and by the general public, that regular collection and cleanly handling of ashes and table scraps is not one of the surest and most profitable ways of protecting health and preventing disease. Efficient administration of this branch of public work should not be allowed to take the place of measures that directly affect the public health.[8]

Few dangers to health have loomed larger in the public eye than that from "sewer gas." Elaborate and amazingly expensive systems of plumbing are required by law to be installed in every newly erected dwelling house in our large American cities. Plumbing inspection today occupies a large part of the working force of many municipal health departments. In Baltimore in 1908, to cite a single instance, this work was carried out by one inspector of plumbing, seven assistant inspectors of plumbing and one drain inspector at a total salary cost of $8,250 or about one tenth of the total salary appropriation for all public health work. And yet, if all the most recent and searching investigations such as those of Winslow and others are to be believed, the actual peril to health involved in the entrance of small quantities of sewer air into houses is so small as to be practically negligible. It may be questioned whether plumbing inspection, as ordinarily conducted, can be shown to save a single life or prevent a single case of disease. There is certainly no reason to suppose that any infectious disease is due to germs carried in sewer air. It might reasonably be maintained that slightly leaky gas fixtures are a much more serious menace to the health of house dwellers than defective plumbing. At all events our present knowledge affords small justification for the expenditure of public money to insure that the odor of peppermint does not enter our houses when oil of peppermint is designedly introduced into the house drains. It may be worth while for the house builder to satisfy himself of the character of the plumbing as of the character of the mortar, but compulsory inspection by public officials is hardly warranted on the ground of a high degree of demonstrated danger to the public health. It is certain, too, that the enforced installation of immensely complicated and elaborate piping and trapping systems simply adds to the cost of building without any compensating hygienic advantages. The plumbing ordinances of our large cities often contain inconsistencies and contradictions, what is required in one city being sometimes forbidden in another. A revision and simplification of municipal plumbing regulations, a minimizing of official inspection and especially an educa-

[8] Any one who fancies that to depreciate garbage disposal as a health measure is flogging a dead horse will be disabused of this impression if he has experience with the beginnings of a typhoid epidemic and learns how often public attention is diverted from significant issues like water-supply, milk-supply, and contact, by appeals to the prejudice against slovenly ways of handling harmless household refuse.

tion of the public to the fact that diphtheria, typhoid fever and scarlet fever have never been definitely traced to sewer air or bad plumbing are reform measures that might release a considerable sum of public money for use in really profitable lines of sanitary endeavor

In the matter of heating and ventilation enormous sums have been spent and are being spent to "renew" the air in rooms and public assembly halls and to introduce "pure air" in what has been assumed to be necessary amounts And yet if the work of Beu,[4] Heymann, Paul, Erclentz, Flugge,[5] Leonard Hill and others means anything it demonstrates that the whole effect from "bad air" and crowded rooms is due to heat and moisture and not to carbon dioxid or to any poisonous excretions in expired air When all the effects of "crowd poison" upon a group of individuals in an experimentally sealed chamber can be eliminated by rapidly whirling electric fans it is useless any longer to look upon carbon dioxid as "a measure of danger" If we recognize that all the discomfort from breathing air in a confined space is due to a disturbance of the thermal relations of the body, the problem of ventilation becomes very different from what has usually been supposed In temperate climates at all events it ought to be much simpler to provide for proper heat regulation of the body than to warm a large volume of outside air and introduce it into a building continuously or at stated intervals It may well be asked whether the elaborate legal regulations governing the "supply" of air and the cubic feet of bedroom space have a real basis in scientific knowledge If over-heating, moisture-content and stagnation of the air are the chief things to be avoided, may this end not be reached more effectively and less expensively than by present methods?

One conspicuous function at present required of or voluntarily exercised by health departments is the practise of terminal disinfection after cases of infectious disease This has come to play a large part in municipal health activities and is responsible for an important share of the expense In Boston, for example, in 1909, about one tenth of the annual appropriation was expended for disinfection One of the most experienced New England city health officers has recently seriously questioned the value of such an expenditure[6] After a study of the ratios of recurrences in certain diseases he concludes that, "Both theory and facts, so far as any data are available, indicate that terminal disinfection after diphtheria and scarlet fever is of no appreciable value" This view has met with strong support from the experience of a number of English health officials, even if it can not be regarded as conclusively proved Every one now knows that the large sums of money spent in measures of disinfection directed against yellow fever gave little return in added safety We can hardly take for granted that any process of combating disease is effectual simply because it is customary or traditional It is evident that the whole question of disinfection needs to be studied afresh with a view to actual efficacy. It is not a subject for laboratory experimentation alone, but must be investigated as a problem of practical public health administration

Other instances of the application of energy and money to measures apparently of slight or doubtful value might be cited, but those already given are fairly typical The question that should be asked in every

[4] *Zeitschr f Hyg*, 1893, 14, p 64
[5] *Zeitschr f. Hyg*, 1905, 49, p 363
[6] Chapin, *Jour Amer. Public Health Assoc*, 1911, 1, p 32.

case is not whether a particular measure is entirely devoid of value, but whether it is the most effective way of utilizing available resources As matters now stand there are a number of unquestionably valuable measures that can not be prosecuted with sufficient vigor because of the enforced diversion of funds into other and less profitable channels

Efficacious measures may sometimes be distinguished from the fruitless or relatively unprofitable by their direct and unmistakable outcome in the saving of life and the prevention of disease. A few illustrations may be noted

The importance of control and supervision of the sources of public water supply has long been recognized, but the importance of controlling the quality of the public milk supply, although frequently urged by sanitarians, is not always appreciated At the present time in the great majority of American cities it is safe to say that for every case of infectious disease due to drinking water ten cases are caused by infected milk It is difficult to secure adequate funds for the sanitary control of the milk supply By sanitary control of milk is meant not the upholding of a rigorous standard of butter fat and total solids, but the maintenance of proper standards of cleanliness and health for dairy cows and especially the safeguarding the milk from infection during collection and transportation. Under some conditions the protection of the consumer against milk-borne infection may be best brought about by compulsory pasteurization of that portion of the milk supply which can not otherwise be raised to proper standard Whatever method of control be adopted, it is certain that any genuine improvement in the character of a milk supply will be followed in the long run by a lessening in the amount of typhoid fever, diphtheria, scarlet fever and to some extent tuberculosis The early detection of a single case of typhoid fever or scarlet fever on a dairy farm may be the means not only of preventing an extensive epidemic, but of avoiding the formation of scores of new foci which can in turn serve to light up subsequent cases for many years Proper pasteurization of milk has been followed in many cities, as in Glasgow, Liverpool and London, by an immediate and material reduction in the amount of typhoid fever In other words, the connection between an expenditure of public money and a direct return in prevention of disease can be more clearly demonstrated in the case of milk-supply control than in some other of the usual municipal health department activities

The question whether the quality of a city milk supply can be more favorably influenced by inspection and supervision at the source, or by generally enforced and controlled pasteurization is one upon which there is still some difference of opinion among experts. There is little doubt, however, that simply as a matter of economy of administration much is to be said at present in favor of centralized pasteurization of a large portion of the supply Viewed as a method for preventing a large number of cases of infectious disease at relatively small expenditure the pasteurization of milk certainly ranks high among effective health measures

One of the important bacteriological advances of the last few years has been the discovery that a considerable number of healthy persons, convalescents or others, harbor disease germs and that these persons are important agents in spreading disease. The detection and proper treatment of disease-germ carriers, particularly in the more serious diseases and before or in the early stages of an epidemic, is now recognized as an important although difficult

task. The whole question of the control of germ-carriers is one that needs more careful study with a view to determining the actual results of the methods adopted. From this point of view, inspection of school children, especially at the beginning of the school year, is probably to be classed as a highly profitable activity, although it is to be wished that fuller and better-studied statistics were available.

Inspection of school children is highly valuable, also, in detecting various common congenital or acquired defects. If the defects are remediable, their early discovery may avoid development into permanently crippling disorders. In other cases, the application of simple corrective or palliative measures may greatly increase the industrial efficiency of the individual. If the defects are not remediable, their detection will at all events prevent the choice of unsuitable occupations, and will indicate desirable lines of education.

In rural communities, undoubtedly one of the simplest, as well as most important, health protective measures is the adoption, under compulsion if need be, of a safeguarded and standardized form of barrel privy.[7] A corollary hardly necessary to mention is the total abolition of the privy in all thickly settled towns. For lack of such regulations soil pollution occurs, the house-fly finds an opportunity to transfer disease germs from excreta to food, and typhoid fever and hookworm disease become constant plagues over wide regions.

In the campaign against tuberculosis it is perhaps too early to evaluate the numerous methods that have been proposed for lessening or eradicating this disease, but it is already evident that some are more directly repaying than others in proportion to the effort involved. Among the methods for which public funds are legitimately available none is more promising than the provision of sanatoria for advanced cases of consumption. Newsholme and Koch have shown that the general diminution in the death rate from tuberculosis observed in most countries can be more reasonably attributed to the establishment of sanatoria than to any other factor, and that in addition to its humanitarian advantages, the segregation and proper control of the advanced and dangerously infective cases is one of the most useful methods that can be employed by the community to protect itself against the spread of tuberculous infection.

Another field in which practical workers are convinced that certain measures have direct efficacy in saving life is that of infant mortality. It has even been said that for the expenditure of a certain sum the saving of a life can be guaranteed. Certain it is, that in few public health activities is the ratio between effort expended and results obtained so clearly seen. No one doubts to-day that prompt notification of births, education of the mother through any one of a number of agencies, and special provision for suitable feeding of infants during hot weather are factors that are bound to tell powerfully in the reduction of infant mortality. It may confidently be asserted that the degree of success achieved in this field will be limited only by the amount of endeavor the community is willing to put forth.

It is impossible at present to apply direct tests of efficiency to some measures that undoubtedly promote health. The influence of playgrounds, public baths, regulation of the hours of labor in extra-arduous industries and the like is real if it can not be accurately determined or estimated.

[7] See Public Health Reports for 1910, published by the Public Health and Marine Hospital Service, articles by Stiles and Gardner, and Lumsden, Roberts and Stiles.

Certain activities of a health department may be worth continuing for their educational value, although their direct utility may be questioned. Many topics need investigation in order to discover their real bearing upon the public health. Among these are such matters as the effect of a smoky atmosphere, the alleged nervous strain due to city noise and numerous important questions in the domain of food adulteration and contamination. Premature and drastic action by health authorities in matters concerning which there is profound disagreement among experts may cast discredit on other lines of activity in which there is and can be no difference of opinion.

For the present it seems worth while to emphasize more sharply than heretofore the distinction between public health measures of proved value and those that owe their existence to tradition or to misdirected and uninformed enthusiasm. Further study of the results obtained by certain of the usual and conventional health department activities is also much needed, and as a preliminary to such study the proper collection and handling of vital statistics is essential. It is poor management and unscientific procedure to continue to work blindly in matters pertaining to the public health, to employ measures of whose real efficiency we are ignorant and even to refrain from collecting facts that might throw light upon their efficiency.

EDWIN O. JORDAN
UNIVERSITY OF CHICAGO

THE ENGINEERING SCHOOL GRADUATE: HIS STRENGTH AND HIS WEAKNESS[1]

So much has been written and spoken of late concerning the success or failure of the various engineering courses in our schools of technology that a reason should be offered for the introduction of this topic at this time. It is to be found, I think, in the general and increasing interest in these matters which is leading the practising engineers, the manufacturers, the men of affairs, in short, the consumers of the product of the engineering schools, to examine and evaluate the work of these schools. This interest has voiced itself more and more freely in the daily press, the engineering journals, and the occasional address. Some of the comments thus made are harshly critical, some are based upon sadly insufficient knowledge of existing conditions, but many are sane and helpful. It is the duty of those of us who are charged with the conduct of those courses to give heed to these utterances and to avail ourselves of the helpful counsel which many afford, but it is also a privilege which we may sometimes allow ourselves to present the case as it appears to us, and this anniversary occasion seems to suggest both retrospection and introspection.

The complexity of the educational problem is nowhere greater to-day than in the training of the engineer, using that term in a broad sense to include the man who applies his science to concrete ends, whether he be, for example, civil engineer, research chemist, or field geologist. The boundaries of all the sciences have been extended at a rate which has far outstripped any reasonable alteration of educational methods to meet these changing conditions, for, over against the charge of undue conservatism which is commonly made with respect to educational practises, should be placed the fact that seven years is the minimum period which must elapse before the ultimate success or failure of an educational experiment can be determined, and since the remodeling of a course or system of

[1] Presented before the Congress of Technology at the fiftieth anniversary of the granting of the charter of the Massachusetts Institute of Technology.

instruction to utilize successfully such of the newly acquired knowledge as it is possible to include must often be the result of gradually accumulated experience, it is plain that rapid and frequent alterations are both unwise and unprofitable. Such advances in scientific knowledge as, for example, those relating to wireless telegraphy, the turbine engine, or aeroplanes, which are of such immediate significance as to seem to imperatively demand a place in our courses of instruction, can not be allowed to displace other older topics of permanent importance, and in many cases these later developments of science are based upon abstruse principles, the proper teaching of which, in turn, demands much time.

The educational problem has, moreover, been rendered more difficult of solution by the concomitant increase in the number of men to be educated. It is no longer possible to give to the undergraduate that measure of personal attention from a mature teacher, of strong personality, which characterized successful teaching in the young manhood of our fathers, and resulted in the production of what may be termed "hand-made engineers." And, again, the increased ease with which our young men can now obtain educational advantages is sending to our schools a much larger proportion of students who, while they are earnest to a high degree and constitute a most desirable class of pupils, have not descended through generations of ancestors with scholarly or scientific instincts, and have not been surrounded by an atmosphere which is at all closely in harmony with that of the lecture room or laboratory. That most of these young men meet with success is the more to their credit, that some others meet with only measurable success in the scientific professions, and that distinct limitations, both professional and social, manifest themselves in the post-graduate development of some, is not surprising, but the cause is often mistakenly ascribed to faulty educational methods when in truth it is far more a question of raw material than of manufacturing process.

The product of the engineering schools has not escaped the universal demand that all products should advance in quality without increase in cost, which, in this instance, means with little or no increase in time expenditure. One needs only to review the conditions of the last quarter-century to realize that an extraordinary change has taken place in the position of the engineer in the community. None of the older professions have been called upon to face such kaleidoscopic conditions and it is not strange that there should be a dearth of men immediately adapted to meet the altered situation, or that many should be found to be partially lacking in the extremely composite training which would lead to complete command of the field. It may not be irrelevant to ask whether the so-called learned professions, so long regarded as superior to the engineering professions, would have fared distinctly better under a like extreme test.

The wholly successful engineer of the day (I do not speak now of the recent graduate) must be a man possessing a capacity for logical, quick and exact thought, a detailed knowledge of some portion and a broad knowledge of the whole of his professional field, and be master of a certain amount of the technique of his profession. He must have the ability to select and guide competent and trustworthy associates and to obtain from them loyal and willing service. He must be strong in his sympathies and generous in his public services, and while quick to enlist desired interest in his enterprises he

must be shrewd in detecting avarice or perfidy He should be a loyal husband and father, and should find opportunity for that enjoyment of art and literature which will afford him present pleasure and ensure the happiness of advanced years It is a matter for sincere rejoicing that the engineering profession has reached such a commanding position in our national life that only a man of this type can completely fill it, but the imperfect portrait just drawn is evidently that of a man for whom nature must have done much at the start, and toward whose efficiency many elements must have contributed Of the need of such men there is no doubt, and it becomes a question of paramount importance to ask how far the engineering schools, as such, or, indeed, how far our entire educational machinery, can contribute to the desired end The most obvious function of the engineering school is to afford a fundamental knowledge and understanding of the principles of the sciences underlying engineering operations Failure to do this seems to be without excuse, yet it is almost inseparable from another important function, namely the development of the power to think (for there can be no adequate understanding of principles unless one can think logically in terms of them when considering concrete problems), and it is just at this point that much of the current criticism is aimed The candid teacher must admit that there is truth in the charge that the graduates are too often lacking both in a capacity for logical thought and in an ability to command the knowledge which they actually possess to the degree needful for immediate or perhaps ultimate success in their vocation. But it should not be supposed that he is indifferent to this state of affairs. It is within bounds to say that it is the supreme desire of every worthy teacher to encourage power of thought rather than mere acquisition of knowledge on the part of his pupils and that he is constantly devising and testing new means to that end, but a moment's consideration will show you how much this depends upon personal contact —now so difficult in even the smallest practicable subdivisions of large classes—and will convince you that there must also be constant conflict of judgment as between the extent of the field to be covered in a given subject (rarely more than the minimum quantity now-a-days) and the time which can properly be spent in that drill which is necessary to develop the powers of the average student, for it is against the average student that the criticism is most valid I do not make these statements to condone the conditions but rather to show you that the teachers recognize them, deplore them, and are striving against them, but the contest is an unequal one, at best.

Let it be remembered, moreover, that some responsibility for these conditions rests upon our public-school system, and also that the sort of thinking which the engineering professions demand is of a kind which is more exacting than is essential in the more common vocations, and that *no* system of education has yet succeeded in training a large proportion of exact thinkers, however much such a result is to be striven for Let us also admit for our encouragement that, after all, there is a considerable proportion of our engineering graduates who *can* use their brains effectively and do have their knowledge in available form, and my observation leads me to believe that there is a much larger proportion who appear deficient in these respects at graduation who develop unexpected power when they have opportunity to concentrate their efforts in a more limited field. Remember that many of these youths have been in some sort of educa-

tional training for a continuous period of fifteen to seventeen years, during which there has been a constant (but sometimes unwise) increase in the pressure put upon them to cover more ground. Is it strange that they have lacked an opportunity to sort their immense stock, or to become familiar with it? They are, I think, entitled to charitable consideration for a time after entering their vocation, but if, as a class, they are deficient after three years, the criticism of them or of their training certainly becomes valid.

The public has a right to look to the engineering schools for sound instruction in fundamentals, including, of course, physics and chemistry, as well as the mathematics and drawing which must form a part of the equipment of every competent engineer. In addition, they may demand that the fundamental principles and something of the technique of those subjects which are of general application within a given profession shall be thoroughly taught, and that this shall be done with reference to development of power and the inculcation of useful habits, rather than the mere acquisition of information. While this is a demand which no engineering school would desire to evade, let us recognize that it is, of itself, no light task to accomplish.

But in our epitome of the distinctly successful engineer of maturer years was included *breadth* of knowledge within and without his profession, the quality of leadership, which means power of initiative and a knowledge of men, and the ability and inclination to fulfill the requirements of good citizenship. Are the graduates from the engineering schools, as a class, in line to develop thus symmetrically? Let us admit again that many are not and that that is the occasion of the general charge of "narrowness" and inadequacy which is directed against our courses. But here again I venture to assert—not, however, in a spirit of complacency—that the situation is more complex than is generally admitted, and that there is a good deal that is encouraging in the situation. Recall once more how short a time it is since the engineer has occupied a position in the community which is recognized to be of equal dignity with that of the so-called learned professions, and recall how recent is that evolution of our industrial system which has as its most important feature the recognition of the fact that the engineer and the financier, if not combined in the same individual, must be on a parity with respect to influence and authority, if efficiency—the watchword of the hour—is to result. Is there not cause for congratulation that some have been found in the engineering ranks capable of meeting this surprising increase of responsibility rather than ground on which to pronounce the general result of engineering education a failure, as some seem inclined to do?

It is well known that the Massachusetts Institute of Technology endeavors to stand to-day, as it has from its beginning, for the largest measure of breadth of training and education which is compatible with thoroughness of fundamental scientific instruction. An inspection of its courses as prescribed for the various professions shows that, notwithstanding the pressure resulting from the growth of science and technology, about one eighth of the total hours which a student spends at the institute is devoted to subjects which are cultural studies, using that term to distinguish them from those scientific subjects which may be regarded as tools of trade, although many of these, notably such as physics, chemistry, biology or modern languages, if properly taught, will contribute much to the cultural development

of the well-rounded engineer and the useful citizen outside of his strictly professional field. In this respect the institute has been a pioneer in engineering education and its founders took a position far in advance of the times Nevertheless the Institute has not escaped the charge of narrowness and this has sometimes come, alas, from some of her own sons who were not over-zealous in availing themselves of the opportunities actually offered during their student days More specifically, as has already been implied, it is charged that the graduates from engineering schools are not as a class showing themselves capable of development into men who can occupy successfully the commanding positions already described, and again the institute is not exempted So far as this charge relates to breadth of view within the professions it is the immediate and vital concern of these schools So far as it relates to those traits which go to make up the accomplished man of affairs it is serious, and demands earnest attention, but the remedies are less obvious, for these remedies must mean the superimposing upon an already heavy burden, a task which should be begun in the home and largely completed there, a task, indeed, which no college has satisfactorily met with respect to all of its professional or non-professional graduates So far as books can help, an added year of student life would seem to afford a remedy and there has been much discussion of the desirability of extending the undergraduate course to five years, and of making the engineering schools graduate schools The arguments can not be reproduced here, but it seems clear that the added expense incurred and the increased age at which the young man enters his life work, militate seriously against the adoption of either of these as a universal procedure. For those to whom such opportunities are open they are likely to prove of great value, and it is interesting to note that each year seems to bring to the engineering schools a larger number of young men who have already graduated from some college, and encouragement is also to be found in the fact that more and more of these men have planned their courses during their college years with reference to later work in the technical school, a procedure which is much more to their advantage than what Professor Jackson refers to as a "butt-joint" between a general college course and a later engineering course It should also be remembered that this is a recent educational development and that these men have not yet been tried out

One serious difficulty which technical schools are encountering has been frequently referred to by recent writers, but deserves a mention here, namely, that of securing and holding broad, cultured teachers Specialization has seriously invaded the teaching profession, especially in scientific lines where the mastery of any large field of knowledge to a degree corresponding to the needs of the expert is rarely possible. The specialist is apt to use the microscope far oftener than the field glass and this habit is partially reproduced in his students. It is encouraging to note that certain schools are now recognizing the need of men who are efficient teachers with a broader outlook, to deal especially with the younger men. They are recognizing that not every eminent specialist or successful investigator is a successful teacher, more particularly in this very matter of breadth of view, and are leaving the specialists greater opportunity for the presentation of their specialties to the older classes, while improving the instruction in the more general courses. It is obvious that these difficulties are enhanced by the larger financial rewards which tempt the broad-minded

engineer away from the schools—a serious matter which can not further be discussed here but lies close to the root of much of the cause for criticism. It is interesting to note how even a single instructor, who keeps himself and his pupils closely in touch with current events, and leads them to understand that no single human attainment, however complete or final it may appear, necessarily represents the best that can be done, and that it may well be the privilege and the duty of any one of his hearers to extend the boundaries of such attainment, will give an impetus to successful effort that will be felt in the entire lives of his pupils. It is to be hoped that no one of us is unable to recall with gratitude some such instructor. We need more of them. A single instructor, again, who exemplifies the cultured scholar and gentleman in ease of manner and grace of diction does more for the cause of scholarship and culture than any quantity of sound advice can do, for, I fear that it is utopian to hope that a majority of the students with whom the study of engineering is the main purpose will ever believe that any man is disinterestedly sincere in his advice regarding such subjects as literature, language, art or economics, unless he makes it quite clear to them that these subjects have a distinct significance to him and are a part of his life. Just here lies one of the great obstacles to the elimination of "narrowness."

If the inculcation of breadth of view and love of the refined in life is difficult, the development of qualities of leadership is even more so. That these qualities are largely conferred at birth will, I suppose, be generally admitted, but I take it that the criticism of lack of leadership is really directed toward an alleged culpable lack of facility in getting the best from others, of appreciating the point of view of others, or of presenting our own views to others. If this indicates a failure on our part to stir the ambitions of our students to avail themselves of opportunities which come to them, or to plan for themselves a really worthy career, then we are at fault, but if it means that the faculties of engineering schools should further encourage those forms of activity commonly designated as "college life," then I believe that we are on debatable ground. Of the importance of those traits which enable a man to win the confidence and respect of his fellow men, to "succeed" among men, no one could be more conscious than I. In individual cases they may indeed be more potent factors than accuracy of scientific knowledge in securing preferment, and any man is fortunate who combines engineering skill with ease of manner and persuasive speech. But the real function of these schools is, after all, the training of capable engineers and it is very easy to pass the line beyond which there is grave danger that both the quantity and quality of individual attainment will be lowered because of time and energies devoted to social affairs. By all means let the schools realize their responsibilities for the development of men as well as engineers, and encourage by precept and especially by example an interest in all that tends toward a better understanding on the part of our students of their human relations, including prudent encouragement of the so-called "student activities." But let those who lack a realization of the great changes which the student life at our technical schools has already undergone in the last few years, and who therefore constantly clamor for more of what is called "college life," reflect that one of the greatest assets which a graduate from one of these schools can take with him when he leaves it is the well-established habit of "doing a

day's work in a day," of meeting his obligations on time, and let him realize that this can not be reasonably demanded if the instructors must in fairness accept excuses because of an undue diversion of time and energy to other things. Although the sciences actually owe many of their advances to "grinds," it is probably fortunate that few of our engineering graduates of to-day belong to that class, but there is little likelihood of an undue increase in the proportion of such over-developed scholars under existing conditions! An impartial survey will, I believe, show that our recent graduates are, as a body, less open to the charge of lack of adaptability, and want of social resources than formerly and that they are improving in this respect as the need of such improvement is more generally realized, and also that there is ground for the belief that this has so far been accomplished without serious sacrifice of professional efficiency.

In what I have just said I have had in mind particularly the business and social relations of the young engineer with his colleagues and superior officers. It is often stated that some or many of the graduates also lack an appreciation of the proper way to deal with those whose labors they must direct. This, again, is doubtless in some considerable measure true, and in fact it can hardly be otherwise when nearly all of these young men pass directly from the public schools to the higher educational institutions. It is not, however, true that no effort is made to bring this phase of their future responsibilities to their notice, for not only is the subject discussed in its general aspects from the lecture platform, but the young men are advised to secure summer employment as far as possible to the end that they may learn to know industrial conditions.

In this connection I should like to point out to those in control of our industrial establishments that there is a large store of energy, combined with a desire for opportunity to work and ability to render intelligent and willing service, which goes to waste in the summer because our students are unable to secure temporary positions. This is particularly true in the industries into which the men in whom I am especially interested, the chemical engineers and chemists, will go. I am, of course, aware that the net return in value to a concern from this temporary service is not relatively large, especially during the first summer, and that in certain industries there is a risk in trusting to the integrity of these men with respect to information acquired regarding operating methods. But I can not avoid the conviction that if the industrial managers would cooperate with the engineering schools in the consummation of an arrangement whereby young men whose ability and character could be vouched for could be given summer employment for two or three of the successive summers intervening during the four years of study, the concerns thus cooperating would actually find that they would derive appreciable benefit from the plan. That it would enable the schools to add at least fifty per cent. to their efficiency so far as these students are concerned, I have no question whatever, and surely no better means could be afforded for the acquisition of a knowledge of the problem of the laborer in the works. Let me add that I do not urge the placing of these young men at once in positions of responsibility but rather in such positions as will afford them working experience under industrial conditions. It seems to me, however, that it is not improbable that, say, in a third summer the majority of such men might be utilized to much advantage in the immediate direction of specific processes or operations,

they themselves acting under general or specific direction.

Some of us are just now concerned to know how with respect to chemical engineering we can give the young men an opportunity to come into contact with the actual practise of their profession before they leave the school, and the advisability of the equipment of laboratories of chemical engineering is under careful consideration. While it is no doubt true that, from its nature, chemical engineering offers less abundant opportunities for industrial work during the vacation interval in a student's career than many other professions, notably less than civil engineering, and at the same time is a profession the actual practise of which it is exceedingly difficult to reproduce in an educational plant, I suspect that similar general conditions exist in other lines. Here, again, is a problem with no small dimensions or importance with which we are wrestling, and one step toward its solution may be made through the greater cooperation on the side of the industrial managers for which I have just appealed.

If I have dwelt more upon the alleged weaknesses of the engineering school graduates than upon their strength, it is because the latter is attested by the engineering advance of the recent past to which they have contributed to an extent which would not have been possible had not the majority of them received from the schools an education and training which has proved useful, dependable and stimulating.

I believe that the large majority of the engineering school graduates are virile, intelligent, industrious fellows, with sound habits of thought and great capacity for work, ambitious to make the best of themselves, possessing a sincere desire to acquit themselves honorably, both in private and public life and with an increasing ability to do so. As such, we, their instructors, honor them and ask your cooperation, advice and encouragement in our efforts to give to them what they deserve at our hands. We ask you also to recognize that while for the moment the rapidly changing social and industrial conditions may have outrun our ability to adapt our educational practise to them, we are not lacking in an appreciation of the significance of these changes, or of our obligations for the future.

HENRY P. TALBOT
MASSACHUSETTS INSTITUTE
OF TECHNOLOGY

CHRISTIAN ARCHIBALD HERTER

THE death of Dr. Herter on December 5, 1910, terminated a life of only forty-five years, a life which had been rich in endeavor and was synonymous with the conception of intellectual cultivation as the happiest outcome of temporal existence.

Dr. Herter graduated from the College of Physicians and Surgeons in 1886 at the age of twenty-one and in the same year married Miss Susan Dows, who throughout his career sustained him with sympathetic power and intelligent appreciation of the value of his work. After graduation he studied with Welch in Baltimore and with Forel in Zurich. He then began to practice medicine, specializing in the diseases of the nervous system, on which subject in 1892 he published his first book. His mind, which was ever active, did not permit him to receive his knowledge through second-hand sources, and in 1893 the upper floor of his house was converted into a series of laboratories in which work could be accomplished according to his liking. It was the beginning of the "Laboratory of C. A. Herter," the contributions of which are known throughout the world. To appreciate the significance of all this, it should be remembered that with the exception of the work in the pathological laboratories of the colleges, the work of the board of health, and the work done by Dr. Meltzer, there was practically no scientific

investigation in medicine worthy of the name in New York city at that time What was true of New York was essentially true of the country at large Here then was one who combined the practice of medicine with the science of medicine as few men of his generation in this country had done Failing strength in his later years caused him to relinquish entirely private practice and devote himself to his laboratory as the center of his intellectual activity It was interesting to note the attitude of an audience when Herter spoke. To many, he was one of them, a practitioner of medicine, and yet to all he was one who had carried medical science to a higher plane, had enveloped medical doctrines with new authority, and the clear, incisive words as they flowed from his lips were followed by his listeners with attentive and almost reverent regard

Dr. Herter found the study of the nervous system so abounding in confusions that he soon turned his attention to chemical problems, especially those connected with pathological conditions Among those intimately associated with him in this work have been E E Smith, A J Wakeman and of late H. D. Dakin Dr Herter's work included researches concerning uric acid, autointoxication, the toxic properties of indol, uremic intoxications, the production of serous atrophy of fat, nitrifying bacteria, acidosis, adrenalin glycosuria, gall-stones, bacterial infections of the digestive tract, intestinal infantilism, the influence of dietary alterations on the types of intestinal flora, and the action of sodium benzoate on the human body The last-named piece of work was part of an investigation conducted by a commission appointed by President Roosevelt, and conclusively demonstrated, so far as physiological investigation can demonstrate, that sodium benzoate if given in the quantities in which it is used as a food preservative, is harmless.

Between 1897 and 1902 Dr. Herter was professor of pathological chemistry at the University and Bellevue Hospital Medical College. Although the lectures were optional, the room was always crowded and his hearers carried away with them breaths of real inspiration. The lectures were published in book form and were translated into Italian In 1903, he was called to the chair of pharmacology and therapeutics at the College of Physicians and Surgeons, a position he held till his death.

He was trustee of the Rockefeller Institute and a moving spirit in the creation of the Rockefeller Hospital Only in the last days of his life was he permitted to see this wonderful hospital accomplished, the dream of many years realized, and almost daily as his strength permitted he would be taken thither to rejoice in its work and its future

He founded the *Journal of Biological Chemistry*, the first of its kind in the English language, and his friends have united in the endowment of this journal as the most fitting memorial to his life's work

Two Herter lectureships, one at the University and Bellevue Hospital Medical College, the other at the Johns Hopkins Medical School, were founded by Dr and Mrs. Herter, and have served to bring to this country many of the greatest scientists in Europe. This has been the public service of a far-seeing mind.

Herter had a wide-spread acquaintance among the scholars of his time both in Europe and at home, and his work and worth were universally respected and admired He delighted in the friendship of those who could inform him, he was a true councillor of those who went to him for advice, and he encouraged young men The blood of the true artist was his Music and painting contributed to the pleasures of his life His friends loved him and he loved his friends GRAHAM LUSK

SCIENTIFIC NOTES AND NEWS

AT its annual meeting on May 10, the American Academy of Arts and Sciences voted to award the Rumford premium to Professor James Mason Crafts "for his investigations in high temperature thermometry and the exact determination of new fixed reference points on the thermometric scale"

THE Academy of Natural Sciences of Philadelphia has elected as correspondents the following: David Starr Jordan, Edmund Beecher Wilson, Jacques Loeb, William Bullock Clark and Thomas Wayland Vaughan.

A complimentary banquet to Professor H. E. Armstrong, F R S., took place at the Hotel Cecil on May 13, attended by a number of distinguished chemists and over two hundred of his former students

At the annual meeting of the British Iron and Steel Institute the Bessemer gold medal for 1911 was presented to Professor Henri Le Chatelier, of Paris The Carnegie gold medal was awarded to Mr Felix Robin, who has conducted researches on the wear of steels and their resistance to crushing Carnegie research scholarships have been awarded to Messrs. W. M. Guertler, of Berlin, G Hailstone, of Birmingham, R M Keeney, of Colorado, and G Dietrich Rohl, of Freiberg Messrs J Newton Friend, of Darlington, and T Swindon, of Sheffield, have had additional grants made to them to enable their researches to be extended and completed

The Association of American Physicians, at its meeting in Atlantic City, elected Dr J George Adami, Montreal, president and Dr Lewellys F. Barker, Baltimore, vice-president

The annual general meeting of the Society of Chemical Industry is to be held in Sheffield on July 12 Dr R Messel has been nominated as president, and Sir William Crookes, F R S, Dr G G Henderson and Messrs H Hemingway and W F Reid have been nominated as vice-presidents

Professor Charles Derleth, dean of the College of Civil Engineering of the University of California, has been elected president of the San Francisco Association of the American Society of Civil Engineers

Dr Francis H Slack, of the University of Kansas, Lawrence, formerly director of the Boston Bacteriologic Laboratory, has been offered the secretaryship of the Boston Board of Health

Dr L. D. Swingle, of Nebraska Wesleyan University, has been appointed research parasitologist in the Wyoming Agricultural Experiment Station

Dr Burt G. Wilder, who last year became emeritus professor of neurology and vertebrate zoology at Cornell University, will hereafter live in Brookline, Mass, where he was born in 1841

Dr F P Gulliver, of the Geological and Natural History Survey of Connecticut and secretary of the section of geology and geography of the American Association for the Advancement of Science, is recovering from a somewhat severe operation that he underwent on May 17

Professor Ernst Haeckel, of Jena, now in his seventy-seventh year, broke his hip bone recently, while standing on a stool to obtain a book from a library shelf

Dean H C Price and Professor W R. Lazenby, of the Ohio State University and Agricultural Experiment Station, have been granted leave of absence for next year, the former for study in one of the German universities and the latter for travel and the study of forestry in Europe and South America

For the year 1911–12 the following will be absent on leave from the University of California: R T Crawford, associate professor of practical astronomy, and G. P. Adams, assistant professor of philosophy. Leave of absence for the first half-year has been given to A C. Lawson, professor of geology, R O. Moody, assistant professor of anatomy; C A. Noble, associate professor of mathematics, and E. E Hall, associate professor of physics; for the second half-year, to D N. Lehmer, associate professor of mathematics.

Professor J. W Beede, of the University of Indiana, will continue his studies of the Permian problem in Oklahoma the coming summer. The work, which will be under the direction of the Oklahoma Geological Survey, will consist in the endeavor to trace the Pennsylvanian-Permian contact from southern Kansas across Oklahoma as far as the Arbuckle Mountains.

Dr Henry Head, F.R S, will deliver the Croonian lectures on "Sensory Changes from Lesions of the Brain" before the Royal College of Physicians of London on June 13, 15, 20 and 27.

EIGHT lectures on the Hitchcock Foundation, at the University of California, were delivered by Professor Harry Fielding Reid, of the Johns Hopkins University, on the evenings of March 28, 29, 30 and 31, and of April 3, 4, 5 and 6 The general title of the course of lectures was "The Mechanics of Earthquakes."

THE annual public address before the chapter of Sigma Xi in the University of California was delivered May 11, by Sir John Murray on the subject of "The Floor of the Ocean" The lecture was illustrated with a fine series of lantern slides largely based upon the results of the Atlantic Expedition of the Norwegian fisheries steamer *Michael Sars* in the summer of 1910

ON the evening of Friday, May 12, Professor G J Pierce, professor of botany in Stanford University, lectured before the society of Sigma Xi of Indiana University on "Vegetation and Civilization"

PROFESSOR ROSS C PURDY, of the ceramics department of the Ohio State University, was recently elected president of the local chapter of the Sigma Xi Society Professor Charles S Plumb was elected vice-president and Professor E F Coddington, secretary

PROFESSOR WAYLAND MORGAN CHESTER gave an illustrated lecture before the departments of geology and biology of Colgate University, on May 25 His subject was "The Bermuda Islands and their Life"

A MONUMENT has been erected at the National School of Agriculture, Montpelier, France, in recognition of the work of the late Gustave Foex, a former president of the school, in improving the culture of grapes

THE Carnegie Fund Committee of France recently awarded the foundation gold medal to the widow of the French doctor, G. E. Mesny, who died while engaged in treating plague victims at Harbin, China.

MRS. WILLIAMINA PATON FLEMING, curator of astronomical photographs in the Harvard College Observatory, died on May 21, aged fifty-four years.

NATHANIEL WRIGHT LORD, for thirty-one years professor of mineralogy and metallurgy, director of the school of mines and first dean of the college of engineering of the Ohio State University, died at his home on May 23, aged fifty-five years

THE New York assembly passed on May 22 the bill previously passed by the senate incorporating the Carnegie Corporation of New York The incorporators mentioned in the bill are Andrew Carnegie, Elihu Root, Henry S Pritchett, William N Frew, Robert S Woodward, Charles L Taylor, Robert A Franks and James Bertram Its purposes are defined as follows "To promote the advancement and diffusion of knowledge and understanding among the people of the United States, by aiding technical schools, institutions of higher learning, libraries, scientific research, hero funds, useful publications, and by such other agencies and means as shall from time to time be found appropriate therefor

THE gentlemen's conversazione of the Royal Society was held at Burlington House on May 10 The fellows and guests were received by Sir Archibald Geikie, K C B, president of the society The Hon R J. Strutt gave a lecture on the afterglow of the electric discharge and on an active modification of nitrogen, and Mr Joseph Barcroft lectured on adaptation to high altitudes in relation to mountain sickness There were as always a large number of interesting exhibits

ADVANCED students or teachers of zoology or botany desirous of working at the Bermuda Biological Station for Research for a few weeks this summer should communicate at once with Professor E L Mark, 109 Irving Street, Cambridge, Mass.

THERE is a vacancy in the Bureau of Soils, United States Department of Agriculture, at Washington, D. C., for the position of soil scientist in the laboratory of physical and chemical investigations. The government is endeavoring to secure the best qualified man available for this work and has no particular individual in view. The position requires a high order of scientific training, equivalent to that required by the leading American universities for a professorship in physical chemistry. As the work will also be largely ad-

ministrative in character, a wide and successful experience in an executive capacity is very essential. A broad field exists for scientific work of a high grade and for original research and investigation which offers rare opportunities for the making of a reputation and for a career in the public service. It is customary to publish the results of investigations in government publications with the name of the scientist making the study or investigation. Those persons who are qualified and who wish to be considered for this position are invited to submit for consideration a statement of their qualifications, references to their published works, and other pertinent material to the United States Civil Service Commission, at Washington, D. C. In general, the methods of procedure in filling this position will be similar to those of an educational institution, whose boards of trustees or governing officers desire to fill professional or technical positions. The qualifications and fitness will be determined by an impartial board of scientists. As the selection for this position will be made about the middle of June of this year, it is suggested that persons interested communicate with the United States Civil Service Commission, at Washington, D. C., at an early date. The entrance salary for this position is $3,000 per annum.

The Health Officers' Association of New Jersey, adopted a constitution and closed its charter membership on May 24, at a dinner and meeting held at Newark. Thirty-three health officers, inspectors and members of local boards of health were present and the association had as its guests two members of the State Board of Health, Col. G. P. Olcott and Dr. R. C. Newton, also Dr. A. C. Hunt, chief of the division of medical inspection; Dr. R. B. Fitz-Randolph, chief of the food and drugs division, Mr. George W. McGuire, chief of the dairy division, and other representatives of the executive staff of the State Board of Health. The objects of the association are the advancement of knowledge relating to the public health, and the promotion of social intercourse among health officials. Five regular meetings in the year are provided for, to be distributed through the winter months. The active membership includes as eligible employees of the state and local boards of health (i. e., health officers and sanitary inspectors), licensed by the State Board of Health, or of the equivalent grade. Members of the state and local boards of health are eligible to associate membership. The officers, elected at a previous meeting, are as follows: *President*, Chester H. Wells, health officer, Montclair, N. J., *Vice-president*, John O'Brien, Jr., health officer, Plainfield, N. J., *Secretary-Treasurer*, J. Scott MacNutt, health officer, Orange, N. J., *Chairman of the Executive Committee*, Dr. Edward Guion, health officer, Atlantic City, N. J.

In 1880 gold was produced in Alaska to the value of $20,000. In 1909 the amount mined was valued at more than $20,000,000. In 1888 silver was first produced in Alaska, to the value of $2,181, in 1909 the value was $76,934. In 1902 copper was first produced, to the value of $41,400, in 1909 its value reached $56,211. These and other statistics of production are shown by Alfred H. Brooks, of the United States Geological Survey, in "Gold, Silver, Copper, Lead and Zinc in the Western States and Territories," published as a separate chapter of the volume "Mineral Resources of the United States in 1909." The Alaska Yukon placer district had in 1909 the most profitable season since mining first began there, a quarter of a century ago. According to the Geological Survey's returns the value of the gold output was $11,580,000, as compared with $10,323,000 in 1908. The production in Seward Peninsula fell off, owing to the facts that many of the richest placers have been mined out and that no preparations have been made for mining the extensive deposits of low-grade gravels. With the construction of large plants an increase may be looked for. The great possibilities of the Alaskan gold-bearing gravels can be recognized when a comparison is made of the recovery from the placer workings of the territory and those of the United States. In 1909 the average recovery for Alaska was $3.66 a cubic yard, while for the United States the recovery was only 12 cents.

UNIVERSITY AND EDUCATIONAL NEWS

MR. T. C. DU PONT has given $500,000 to the Massachusetts Institute of Technology toward its proposed new site. Announcement is also made of two bequests of about this amount: a trust fund of between five hundred and six hundred thousand dollars, created by Francis B. Greene some five years ago, will be received by the institute for the assistance of students, and it will receive nearly $500,000 from the bequest of Mrs. Emma Rogers, widow of William B. Rogers, the first president of the institute. These large gifts in addition to the $100,000 for ten years appropriated by the state, will make it possible for the institute to purchase a new site and erect the necessary buildings.

BY the will of Mrs. Lydia Augusta Barnard, of Milton, Mass., Radcliffe College received $75,000 for a dormitory and $40,000 for scholarships, and Harvard University receives $60,000 for the study of jurisprudence and legislation.

THE Harvard College corporation has voted to approve the establishment of a school for advanced instruction in medicine in general accordance with a plan proposed by the Faculty of Medicine, the intention is that the school shall go into operation at the beginning of the academic year 1912–13, that it shall have a separate dean and administrative board, and that it shall ultimately absorb the Summer School of Medicine. Instruction in the school is to be provided if possible by the existing departments of the Medical School, but, if necessary, instructors will be appointed specifically for giving instruction in the new school. The courses of instruction will consist of all-day courses, intermittent courses and research courses.

THE preamble of the statute exempting students in natural science and mathematics from examination in Greek passed congregation at Oxford on May 16 by a vote of 156 to 79.

PLANS for the extension of the work of the department of physiology of Columbia University are being carried out. Three additions to the staff have been made: Frank H. Pike, of Chicago University, to be assistant professor; Horatio B. Williams, of Cornell, to be an associate, and Donald Gordon to be an instructor. Dr. Williams is spending the summer in Europe visiting several laboratories and arranging for the purchase of apparatus for electrocardiographic and other work. Professor Burton-Opitz will have charge of the instruction of the medical students and Professor Pike of much of the work in general physiology. A course in clinical physiology, dealing with the application of physiological methods to problems of clinical medicine has been established. Changes in the laboratories will be made during the present summer. The income of the George G. Wheelock Fund is to be devoted to the extension of the library. The chief professorship of physiology, held by Frederic S. Lee, has been entitled the Dalton Professorship, in memory of John C. Dalton, who was in point of time the first experimental physiologist of America and gave distinguished services to the Columbia School of Medicine for thirty-five years.

DR. S. O. MAST, professor of botany at Goucher College, has resigned in order to accept an associate professorship in zoology in the Johns Hopkins University. He will take up the duties connected with his new position at the opening of the next school year.

AT the University of California J. G. Fitzgerald has been appointed associate professor of bacteriology, J. Frank Darnel, assistant professor of zoology, and A. U. Pope, assistant professor of philosophy. Instructors have been appointed as follows: C. J. Lewis, in philosophy, Frank Irwin and Thomas Buck, in mathematics, C. L. Baker, in mineralogy and geology, D. W. Morehouse, in astronomy.

DISCUSSION AND CORRESPONDENCE

THE TEST OF VITALISM

TO THE EDITOR OF SCIENCE: Such attempted definitions of vitalism as those furnished by your correspondents fail to give a clear conception of the idea usually conveyed by the word. Its real significance, I think, is better

expressed by a hypothetical test. Assume any healthy organic cell or organism to be instantaneously resolved into its constitutent particles so that they are suddenly reduced to inorganic substances Then assume that it were possible to instantaneously reassemble each of these particles in precisely the physical relations in which they before stood to each other with the same temperature conditions and let each particle be instantaneously impressed with motions the same in direction and amount which they possessed at the instant of dissolution If then the reassembled body goes on as an organism as before, it will be proof that life is but the operation of what are known as the ordinary mechanical and chemical forces If not, it will be proof that a certain tertium quid no matter what is lacking to convert the body into an organism This tertium quid constitutes the element of vitalism as it is generally understood It does not necessarily imply the imposition of some new and foreign principle or substance on the materials constituting the body It may be nothing more than the bringing into activity of forces or affections previously latent in the materials themselves. The former seems to be the theory of the extreme vitalists who look on the soul as something distinct from the body, while the latter seems to correspond with the views of those vitalists who regard matter as in the language of Tyndal impressed with the potency of all life.

In a last analysis, however, no sharp line of distinction can be drawn between the vitalists of the latter type and the non-vitalists. For it seems clear that if this tertium quid be in any manner latent in the inorganic particles, it may be looked on as undisclosed chemical attributes of the matter itself. It becomes rather a question of definition, what are chemical or mechanical attributes? These terms in their popular significance are confined to forces subject to comparatively simple mathematical laws. I think few mathematicians would concede that such laws, however numerous, could furnish an equation which would satisfy the complicated movements involved in the life history of an organism. The forces at work must be something more than those ordinarily understood as mechanical or chemical.

When to this is added the element of self-direction or self-selection, which in its higher forms assumes the aspect of self-consciousness, we have crossed a barrier which apparently can never be bridged in terms of mechanical or chemical forces and which must seemingly forever remain a mystery, whose solution we are no nearer than were the old Greek philosophers The weight of such evidence as we have seems to favor a modified vitalist or it might be called mechanical vitalistic view All vital activity is measurable in terms of energy expended. An infinite chain of physical causation determines every vital movement. No power of self-determination beyond such causation could exist without the power to create energy. The activity of the organic mechanism may be suspended indefinitely and again revived if no disarrangement of its constituent particles occur On the other hand, no mathematical laws can be conceived of which could express the operation of the forces which direct the life history of the individual Are we not brought back to the old theistic or deistic conception of an inscrutable power pervading all nature in whom we live and move and have our being?

A PLEA FOR THE USE OF REFERENCES, AND ACCURACY THEREIN

TO THE EDITOR OF SCIENCE. It has been the writer's duty, during the past two or three years, to compile, or to assist in the compiling of, a number of extensive bibliographies and lists of references to the literature of various chemical subjects, and during this work it has been often impressed upon him with what laxity and apparent disregard of consequences some authors handled—or failed to handle—their references to prior work. The same difficulty is all too often experienced when looking up some apparently simple subject.

For instance, an article was recently desired by a chemist employed in certain synthetic

work, describing a method for the reduction of certain compounds, referred to in a scientific paper, without further information, as "Ladenburg's" method Persistent search of the indices of the journals where the paper would most probably have appeared yielded only a brief polemic note, *which made no reference to the appearance of the original paper!* The proper method was finally found as a side-issue in a paper on oximes, through the use of a very recent hand-book of laboratory methods, the author of which had very probably gone through the publications of Ladenburg until he struck this article Had the author of the paper from which the reference (?) mentioned in the first sentence of this paragraph taken half a minute's more time and given this reference, and given it correctly, he would have saved others literally hours of searching

Another instance. Certain important and excellent work was recently done in Philadelphia on methods of sewage disposal As one feature of this work, a large number of determinations of the amounts of nitrates present were made by what was referred to as "McRae's narcotine test," no reference or description of the method being given. It became necessary elsewhere to find the details of this method, and it so happened that the usual chemical abstract journals had missed this paper. As a last resort, the "Index Medicus" was looked through, and finally a reference to the paper was found, though even here the citation given was not the one where the paper would usually be most easily found Had the author of the report of the Philadelphia experiments given a half-line reference to the place of publication of this method, he would have saved an hour or more of the time of one or two men in a busy laboratory

Fortunately, cases of the total omission of an important reference are comparatively rare, though the embarrassment and additional work such omissions cause is quite sufficient to warrant their being judiciously guarded against. More frequent, and sometimes equally troublesome, are the cases where erroneous page, volume or year numbers are given, or sometimes even an erroneous journal or book name A case recently shown me was that of an author who referred some eight or nine times in a paper of four pages, to the work of another author "Schreiber",—"Schreiber's" correct name was "Fleischer"!

The movement for the unification and coordination of zoologic nomenclature, although differing in many considerable respects from what a similar movement in other sciences would be, includes not a few phases which could well be studied and adopted by non-zoologic contributors to the literature of science.

A TREMATODE EPIDEMIC AMONG ENGLISH SPARROWS

DURING the months of June and July, 1910, English sparrows in the vicinity of the College of Agriculture of the University of Wisconsin at Madison were found to be very commonly infected with a trematode parasite which was identified as *Monostoma faba* Bremser This parasite, which forms conspicuous cysts in the skin of the abdominal region, has long been known in Europe, but has heretofore been reported in only one or two isolated cases on this continent. Attention is called to the matter here, as it may be of general interest to helminthologists, and in order that others may be on the lookout for the parasite in this country. In this locality the parasite appeared to cause a certain mortality, and it is possible that it may become one of the means which will help to check the increase of the English sparrow in North America. Unfortunately, it attacks other small passerine birds of several families as well. A more detailed account of the present epidemic is being published in the *Bulletin of the Wisconsin Natural History Society*, Vol. 9, Nos 1–2, pp. 42–48, pl. 5, April, 1911

REFORMED CALENDAR

A CALENDAR project which ignores the immutable character of the week has slight chances of being adopted because the week is fixed by religious observance in all christian nations The calendar here proposed is based on the week as a fundamental unit It is closely similar to the calendar recently proposed by Dr C G Hopkins, but differs in that it consists of a year of thirteen months, each four weeks in length, instead of Dr Hopkins's twelve months divided into quarters of three months, each quarter containing two four-week months and one five-week month Dr Hopkins's reason for retaining twelve months is that the quarters of the year may be even months, but the value of the quarter year as a unit of time is incomparably less than the value of the month It is highly desirable to have all the months the same length for the reason that salaries, wages, rent. board and many other ordinary affairs are counted in months The advantage to be gained by having months of uniform length is one of the most marked advantages to be gained by a reform of the calendar

In the present project the new month is inserted between June and July This is the month in which the summer solstice occurs in the northern hemisphere and the winter solstice in the southern hemisphere, hence it may properly be called "Sol"—the month of the solstice

In the new calendar the quarters are easily found, as each consists of thirteen weeks The four quarters would end on the following dates first quarter, April 7, second quarter, Sol 14; third quarter, September 21, fourth quarter, December 28, and these dates would all be Sunday in the new calendar. The present project therefore contains all the advantages of Dr. Hopkins's project, and the additional advantage of having all the months the same length, as well as multiples of the week

Other advantages of the new calendar are: the year always begins on Monday, every month begins on Monday, the same day of the year always occurs on the same day of the week, the same is true of the days of the month Thus, the first, eighth, fifteenth and twenty-second of every month would fall on Monday, the seventh, fourteenth, twenty-first and twenty-eighth of every month would fall on Sunday.

If desired Sunday may as well be taken as the initial day of the week, month and year

An additional advantage is that a calendar for one year is good for all future time, as the years are all alike in all respects except that every fifth year has an extra week added to December, with exceptions noted below

The details of the project are as follows

Common years consist of thirteen months of four weeks each, namely, January, February, March, April, May, June, Sol (the month of the solstice), July, August, September, October, November and December;

Long years differ from common years in having an extra week added to December,

Years divisible by five are long years, with the exceptions noted below

The extra week is omitted from years divisible by 50 It is also omitted in the year '25 following centennial years divisible by 400, and in the year '75 following centennial years divisible by 25,000. This makes a calendar good for more than 300,000 years

In order to cause less confusion, this calendar should be adopted in a year that begins on Monday In the near future these years are 1912, 1917 and 1923.

In order to secure the adoption of a reformed calendar, we must secure the appointment of an international commission with representatives from all civilized nations. It seems to me that our present duty is to begin a serious attempt to secure the appointment of such a commission Can we not form an organization for this purpose?

W J. SPILLMAN

WASHINGTON, D C.

QUOTATIONS

THE SCIENCE MUSEUM AND THE NATURAL HISTORY MUSEUM

DURING the past few weeks we have printed letters from several distinguished correspon-

dents dealing, from various points of view, with the very serious question that has arisen between the Office of Works and the trustees of the Natural History Museum concerning the respective claims of that museum and of the adjacent Science Museum to what remains still unoccupied of the space which separates the one from the other. No one can think that the buildings in which the Science Museum is at present housed are worthy of the dignity of science, or of their position as associated with the central home of science in the capital of a great empire. Every one should approve, therefore, of the recent appointment of a committee by the president of the board of education to consider the demolition of existing buildings and the construction of a new Science Museum on a scale worthy of its purpose and character. But it would appear from the recently published official correspondence between the Office of Works and the trustees of the Natural History Museum that this committee is only empowered to consider the construction of an enlarged Science Museum on the site now occupied by the unworthy and unsightly buildings which now go by that name. It is clear, however, that this can not be done—for on this point, at any rate, the Office of Works and the trustees are in full agreement—without encroaching on the space required for future enlargements, already urgently needed, of the Natural History Museum, and in fact on space which after much correspondence between the trustees, the Office of Works, and the Treasury, was formally allotted in 1899 to the Natural History Museum for that purpose. In the interest of the new Science Museum the Office of Works now proposes to resume possession of a strip some seventy feet wide and some 1,200 feet long, running the whole length of the north side of the area hitherto allotted to the Natural History Museum. This strip is at present occupied as to some portion of its length by a Spirit Museum—that is, a building for the storage and exhibition of specimens preserved in spirit, 145,000 in number, contained in 95,000 jars, many of large size—which has been erected and fitted up within recent years at a total cost of no less than £38,000. It is now proposed that, as soon as the Spirit Museum has been removed to a new and very objectionable site, a portion of this strip some forty feet wide should be assigned to the new Science Museum, while the remainder, some thirty feet wide, is to be converted into a private road separating the two museums.

It should surprise no one that the trustees should, as they say, view these proposals "with extreme apprehension." The only wonder is, perhaps, that the Office of Works should ever have entertained them seriously. It was originally proposed that the total area to be assigned to the Natural History Museum should be about fifteen and a half acres, and the steady growth of the museum in recent years has shown that this was not a yard too much. By the arrangement of 1899, to which we have already referred, this area was reduced to a little over thirteen acres, and it is now proposed to reduce it by very nearly two acres more, although, as the trustees point out, the reduced area of 1899 was accepted on the understanding that it was their intention to use the land in question for the further extension of the Spirit Museum, and "it can only have been by reason of such understanding that the trustees felt justified in accepting that line of boundary as a final settlement of the question." Yet if the Office of Works is to have its way, that final settlement is now to be treated as no settlement at all. The northern boundary is to be set back by seventy feet; the Spirit Museum is to be abolished and reerected facing Queen's Gate in such a position on the vacant space still surrounding the Natural History Museum as grievously to impair the symmetry and sightliness of any future extension of the latter; and the Science Museum and the Natural History Museum are to be left and even encouraged to approach each other from the north and south respectively in such a manner as may and probably will leave in the end only a private road some thirty feet wide between them. We can hardly believe that parliament and public opinion will ever sanc-

tion these extraordinary and most objectionable proposals. To judge from the correspondence which we have printed on the subject, they appear to find favor with no one—for even Sir Henry Roscoe could only find something to say for them by making a suggestion for the removal of the Spirit Museum to a distant site which other equally high authorities have shown to be inadmissible—and they have elicited protests of unanswerable cogency from naturalists of such high authority as the master of Christ's and Dr. Gilbert Bourne, as well as from the Linnean Society, the Entomological Society, and the Royal Horticultural Society. Moreover, the emphatic protests on other grounds and from other points of view of Lord Wemyss and of Lord Dufferin and those associated with him are by no means to be overlooked.

The plain truth is that, as the trustees put it in their final letter to the Office of Works, "to attempt to accommodate three important institutions, the Natural History Museum, the Imperial College of Science, and a much enlarged Science Museum, on so restricted a site shows a want of appreciation of the inevitable future of these institutions which is bound to lead to confusion and a waste of public money. Not only the Natural History Museum, but all three institutions, would soon be hampered in their growth." The propositions here advanced scarcely admit of dispute. The trustees point out that they have recently been enabled by the government to purchase land at Bloomsbury sufficient to provide for the extension of the departments located there in such a manner as to satisfy prospective needs of those departments for 100 years to come. Yet all that the Office of Works can say on behalf of its unhappy scheme for extending the Science Museum at the expense of the Natural History Museum is that "the vacant space to the east and west of the Natural History Museum is so great that it is hardly possible to suppose it will not afford abundant facilities for any extension of the Natural History Museum which may be required for the next twenty-five years"—which is just a quarter of the period for which the government have empowered the trustees to make provision at Bloomsbury. The comment of the trustees on this significant contrast appears to us to be quite unanswerable. They "feel bound to protest against the reversal at South Kensington of a policy so carefully considered and so universally endorsed"—as regards the departments at Bloomsbury, that is—"and they can not therefore, with due regard to their responsibilities, consent to give up land which will be urgently required in the near future for the extension of the Natural History Museum." To this most reasonable *non possumus*—reasonable because based on indisputable facts as well as on the authority of all competent experts—the Office of Works could only reply by a departmental *hoc volo, sic jubeo,* backed by the authority of the government. "The question of the revision of the boundaries has been considered by his majesty's ministers, and they have decided that such a revision can not be avoided in view of the pressing necessity for the building of a Science Museum." So far as we are aware no one disputes the pressing necessity for the building of a Science Museum. But surely no one who has studied the official correspondence or who has followed the discussion in our columns can defend or approve the policy of building such a museum at South Kensington in such a manner as must fatally hamper its own expansion and that of the Natural History Museum in the near future. There is manifestly no room for all three institutions on the same site. Two of them are there already, therefore the third must go elsewhere. That is the only rational solution of the problem, and it certainly ought not to be rejected by the mere fiat of his majesty's ministers without giving parliament and public opinion an opportunity of pronouncing judgment on the matter.—London *Times*.

SCIENTIFIC BOOKS

The Principles and Methods of Geometrical Optics. By JAMES P. C. SOUTHALL. 8vo. Pp. xxiii + 626. New York. The Macmillan Company. $5.50 net.

Professor Southall, in his book on geometrical optics, undertook to put in one volume most of that which is valuable on the subject, especially as applied to optical instruments He was filled with enthusiasm, inspired by a sincere belief in the value of the subject and an ambition to supply the admitted deficiency in the English language

Partly with the object of supplying this deficiency, and partly also in the hope (if I may venture to express it) of rekindling among English speaking nations interest in a study not only abundantly worthy for its own sake and undeservedly neglected, but still capable, under good cultivation, of yielding results of far reaching importance in nearly every field of scientific research, I have prepared the following work .

It is such enthusiasm as this that holds one to the severe labor of preparing a large book and of making it a good book While it is doubtful whether any large number of scientific men will follow Professor Southall in his very high estimate regarding the relative value of geometrical optics and in his optimism respecting its future, the careful and exhaustive book which he has prepared will undoubtedly do much to bring the geometrical theory of optical instruments into greater favor in this country

Professor Southall treats in successive chapters the fundamental properties of geometrical optics, the properties of rays of light, reflection and refraction at a plane surface, refraction through prisms, reflection and refraction of paraxial rays at a spherical surface, refraction of paraxial rays through thin lenses, the theory of optical imagery, lenses and lens systems, exact trigonometrical formulæ for tracing rays through spherical surfaces and centered systems of spherical surfaces, theory of an infinitely narrow bundle through an optical system, theory of spherical aberrations including Seidel's theory developed to aberrations of the third order, color-phenomena and chromatic aberrations, aperture, and field of view and brightness of images. It is seen from this how extensive is the subject-matter treated. In general, all the chief discussions of the more important topics have been given This has led to a duplication in very many instances; particularly, many subjects are treated both geometrically and analytically This, of course, is not to be regarded as a positive fault in an exhaustive treatise, for the one method will appeal to some and the other method to others. But probably many will wish, on reading the book, that especially the first part had been written more concisely and with fewer repetitions of subject-matter under different forms This would not be, however, in harmony with the obvious plan of reproducing essentially all that is of value in the subject The alternate plan is to adopt a definite point of view and to develop the subject systematically from that point of view

Probably the greatest service rendered by Professor Southall has been in setting forth clearly and consecutively the splendid optical theories of the German writers of the last half century, particularly those of Seidel and Abbe His book may inspire us to divide with the Germans the future developments in these lines At any rate all who have an interest in the subject will thank him that he has so well done his part, for it will not be questioned that he has prepared the best and most exhaustive work on geometrical optics in the English language. So far as the question of completeness is concerned there seems room for regret, and that mostly on the part of practical opticians, only in that the theories are not illustrated more by numerical examples based on the glasses of commerce

F. R MOULTON

A Laboratory Manual of Inorganic Chemistry By EUGENE C BINGHAM, Ph D. (Johns Hopkins), Professor of Chemistry, Richmond College, Richmond, Va, and GEORGE F. WHITE, Ph D. (Johns Hopkins), Associate Professor of Chemistry, Richmond College, Richmond, Va. New York, John Wiley & Sons; London, Chapman and Hall, Limited. 1911. 12mo, pp viii + 147 Cloth, $1.00 net (4s. 6d net).

In the preface the authors state that, in their opinion, "a course in inorganic prepara-

tions and systematic qualitative analysis, with a few carefully chosen quantitative experiments afford the best background for the theoretical development of the science." They have, in order to avoid superficiality, cut the number of experiments down to a minimum, necessary for the understanding of the subject in its elementary phases. They have given more experiments than can be done in the normal year's work in school or college, hoping to stimulate the ambitious student to further work.

They have selected 33 typical experiments which includes the preparation of the common gases and acids and the preparation of several salts. This is followed by a study of the typical reactions of the metals and a course in qualitative analysis. The book also contains a few pages devoted to the quantitative proof of some of the fundamental laws upon which the science of chemistry is based. The material given is well selected and clearly stated, though, as the authors state in the preface, they have introduced little that is new. The question that each teacher must solve is whether it is better to cover a limited field thoroughly or to cover a broad field by selected examples. If a student's knowledge of chemistry is to be gained by one year's work this book could be used no doubt to advantage in connection with a text-book and a course of lectures; but if the subject is to be pursued further each one of the separate fields covered here would have to be gone over again in greater detail in order to attain a suitable ground for more advanced work.

J. E. G.

A Naturalist in the Bahamas. By JOHN I. NORTHROP. October 12, 1861–June 25, 1891. A memorial volume edited with a biographical introduction by HENRY FAIRFIELD OSBORN. New York, The Macmillan Co. $2.50.

The present volume brings together the papers of the late Dr. John I. Northrop, describing the zoological, botanical and geological results of his six months' collecting on the Bahama Islands. It includes also a narrative of the expedition contributed by Mrs. Northrop; a report upon the Bahaman crustaceans by Professor William H. Rankin; on the actinians, by Professor J. Playfair McMurrich; on the shells by Professor William H. Dall, on plants by Mrs. Northrop, Mr. Frank S. Collins and Dr. O. F. Cook, and a paper describing the new oriole *Icterus northropi*, by Dr. J. A. Allen. All of those papers are carefully republished and the volume forms altogether a substantial contribution to American zoological literature. . . One closes the book with the feeling of keen regret that the life of Dr. Northrop could not have been spared. If his early promise brought together both from his own pen and from those of his associates the present results, what may not his years of maturity have contributed? He was another Lycidas and zoologists will remember him with such men as Harrington, Budgett and Balfour.

BASHFORD DEAN

THREE FORMICID NAMES WHICH HAVE BEEN OVERLOOKED

MR. S. A. ROHWER has kindly called my attention to two generic names which have been overlooked by all recent myrmecologists, including Dalla Torre, the author of the "Catalogus Hymenopterorum." One of these names is *Typhlomyrmex*, which was given by Gistel in 1856[1] to *Myrmica typhlops* Lund. On referring to Lund's paper[2] I find that *M. typhlops* is mentioned without a description, and since the insect is certainly not a *Myrmica* in the modern sense and can not be identified from the few notes on its habits (moving in files and carrying isopods), the name must be regarded as a *nomen nudum* and hence without any standing in nomenclature. And since Gistel cites no characters for his genus *Typhlomyrmex* but merely bases it on an invalid name, it, too, is without standing. Mayr, without knowing of Gistel's work, described in 1862 a genus *Typhlomyrmex* for a neotropical ant, *T. rogenhoferi*

[1] "Mysterien der europäischen Insectenwelt."

[2] "Lettre sur les Habitudes de Quelques Fourmis du Brésil, addressée a M. Audouin," *Ann. Sci. Nat.*, XXIII., 1831, p. 113–138.

Mayr. A few other species have since been added. It is clear that *Typhlomyrmex* Mayr is valid and not to be replaced by some other name on account of Gistel's *Typhlomyrmex*, which has not even the status of a synonym.

More serious is the second case which involves *Polyrhachis*, an important genus comprising some 300 known species of paleotropical ants. The name *Polyrhachis* was first suggested by Shuckard in a volume which he published with Swainson in 1840.[3] On page 172 of this work occurs the following sentence: "It is in the first division that we find the stingless genera, namely, *Formica* Linn., *Formicina* Shkd., *Polyergus* Latr., *Polyrhachis* Shkd. and *Dolichoderus* Lund, besides several other yet uncharacterized genera which we shall shortly publish." As Shuckard did not live to give a description of *Polyrhachis* and cites no species as belonging to it, the name is merely a *nomen nudum*. It was, however, either resuscitated or reinvented in 1858 by Frederick Smith.[4] He described some twenty species of *Polyrhachis*, with Drury's *Formica bihamata* as the designated type. In the same year 1858 Gerstacker[5] based a genus *Hoplomyrmus* on an African ant, *H. schistaceus* Gerst., which is clearly congeneric with the forms included by Smith in *Polyrhachis*. As Emery has shown,[6] there is some doubt as to which generic name was first published. Since Smith's paper was read before the Linnean Society in June, 1857, while Gerstacker's was not read before the Berlin Academy till April, 1858, the genus *Polyrhachis* has been given precedence by subsequent writers. Emery has, however, adopted *Hoplomyrmus* as a subgeneric name for a number of species which he groups together as the cohort "Polyrhachides carinatæ."

[4] "Catalogue of the Hymenopterous Insects Collected at Sarawak, Borneo; Mount Ophir, Malacca; and at Singapore by A. R. Wallace," *Journ. Proc. Linn. Soc. Zool.*, II, 1858, pp. 42–130, 2 pls.

[5] *Monatschr. Akad. Wiss. Berlin*, 1858, p. 262.

[6] "Saggio di un Catalogo Sistematico dei Generi Camponotus, Polyrhachis e Affini," *Mem. R. Accad. Sci. Ist. Bologna*, 1896, p. 776 nota.

Speculation on the validity of *Polyrhachis* and *Hoplomyrmus* loses all its significance in the light of Mr. Rohwer's discovery that Billberg in his "Enumeratio Insectorum" published in 1820, a work of which there seem to be only two copies in America, one in the Museum of Comparative Zoology, the other in the library of the Boston Society of Natural History, had many years previously established the genus under another name. In this work on p. 104 we find the following:

"G. Myrma Eg.—Formica ol.
Carinata N. Chaled. Fbr. | Hystrix Eg. 2"
militaris Afr. Aequin. — |

The "Eg" in this citation stands for "Billberg." It is clear that this author cites the two valid Fabrician species *Formica carinata* and *militaris* as representatives of a new genus *Myrma* for what was formerly a portion of the genus *Formica* Linn. Both of these species have long been regarded as *bonâ fide* members of the genus *Polyrhachis*, which, as has just been shown, was not established till 1858. The *hystrix* cited by Billberg is a *nomen nudum*, if it be not the *Formica hystrix* of Latreille and Fabricius, which is in turn a synonym of *Atta* (*Acromyrmex*) *octospinosa* Reich. The "Eg" after the name would seem to preclude this latter supposition. Be this as it may, however, there can be no doubt concerning the two other species, one of which, *F. militaris*, may properly be regarded as the type of the genus *Myrma*. This case seems, therefore, to be quite clear and to require, in obedience to our code of zoological nomenclature, the substitution of *Myrma* for *Polyrhachis*. Although this is a deplorable change, owing to the large number of citations of ants under Smith's generic name, there is, nevertheless, a slight gain in brevity and euphony. I would suggest, however, that *Polyrhachis* Smith be retained as a subgeneric name for the type *P. bihamata* Drury and the small cohort of allied species (*bellicosa* F. Smith, *ypsilon* Emery, *craddocki* Bingham and *lamellidens* F. Smith) which Emery calls Polyrhachides hamatæ. The typical subgenus *Myrma* will replace *Hoplomyrmus*,

since its type, *M. militaris*, is closely related to Gerstacker's *schistacea*.[7] The species of *Myrma* may then be grouped under several subgenera, names for two of which are here suggested for the first time, as follows:

Genus Myrma Billberg (1820) = *Polyrhachis* F. Smith (1858)

1. Subgenus *Campomyrma* subgen. nov.
   = Cohors Polyrhachides camponotiformes Emery
   Type *Polyrhachis clypeata* Mayr
2. Subgenus *Myrma* Billberg = *Hoplomyrmus* Gerst.
   = Cohors Polyrhachides carinatæ Emery
   Type *Formica militaris* Fabr.
3. Subgenus *Polyrhachis* F. Smith
   = Cohors Polyrhachides hamatæ Emery
   Type *Formica bihamata* Drury
4. Subgenus *Hagiomyrma* subgen. nov.
   = Cohors Polyrhachides arciferæ Emery
   Type *Formica ammon* Fabr.
5. Subgenus *Hemioptica* Roger
   Type *Hemioptica scissa* Roger.

A third generic name, *Formicina* Shkd., which has been overlooked, is mentioned in the foregoing citation from the work of Swainson and Shuckard. This citation and the context seem to show that Shuckard accepted *Formica* Linn. in a restricted sense as the equivalent of what we now know as *Camponotus* Mayr, probably with the type *Formica herculeana* Linn., but this is open to doubt since no species is cited. On the same page two well-known ants are mentioned as species of *Formicina*, viz., *F. rufa* Linn. and *F. flava* Fabr. If only the former species had been mentioned, we might have been compelled to change our modern genus *Formica* to *Formicina*, but as Shuckard included also *F. flava* (which is at present *Lasius flavus*) in the same genus, we see that *Formicina* is merely a synonym of *Formica* as used by Fabricius and his contemporaries, possibly *minus* the group now known as *Camponotus*. Under the circumstances I can see no reason to replace any of the modern subdivisions of the old Linnean genus *Formica* with *Formicina* Shuckard.

W. M. Wheeler

[7] According to Emery *schistacea* is merely a subspecies of *militaris*.

ON MUSCOID AND ESPECIALLY TACHINID SYNONYMY

The time seems ripe for a few remarks on this subject. There exists in the superfamily Muscoidea an immense taxonomic field awaiting exploitation, and it is to be hoped that it will attract many able workers imbued with a proper sense of responsibility, for it is at the same time a biologic field of first importance and magnitude as regards arthropod and general invertebrate evolution. Only one caution is necessary to those who would enter this field, as well as to those already in it—and this applies as well to all workers in whatever field—which is to do one's work so thoroughly as to secure absolute finality before drawing positive conclusions. In other words, do not make an unqualified statement before going to the bottom of the matter in hand. Results secured during the past three years have demonstrated conclusively that finality in the taxonomy, and consequently in the synonymy, can not be secured in this superfamily by the off-hand comparison, or even by the most careful study, of external adult characters alone.

Mr. D. W. Coquillett, in his "Revision of the Tachinidæ of America north of Mexico,"[1] without the knowledge just mentioned and thus without any true conception of the great difficulties before him, moreover without a good eye for external characters and with little appreciation of their importance, but nevertheless with the best of intentions, attempted to group these flies comprehensively and indicated extensive but often incorrect synonymy, lumping even distinct genera under one species in the most uncouth but seemingly plausible manner. We can not but admire the industry and ingenuity which have contributed to produce this work, while we deplore its great lack of quality. Dr. J. M. Aldrich, in his "Catalogue of the North American Diptera,"[2] also without the above knowledge but with a somewhat better eye for external characters, though following Mr. Coquillett quite faithfully in the main, has resurrected a few

[1] Techn. Ser. Bull. No. 7, Div. Ent., U. S. Dept. Agr., 1897.

[2] "Smiths. Misc. Colls.," No. 1444, 1905.

species from the latter's synonymy My own publications on the subject, which have been quite extensive and in which I have proposed many new genera and species, no small part of which may quite possibly have to go in the final synonymy, were produced almost in whole without the above knowledge but with a very considerable appreciation of the necessity for a most careful and minute comparison of external characters Brauer and von Bergenstamm's monumental work, performed under the same conditions, and unquestionably the best and most advanced of all, must be classed here too, along with all other taxonomic work in the Muscoidea to 1908 The results in all these cases have been quite unfortunate, considering the amount of time and energy expended All the material handled by Mr Coquillett will have to be restudied with great care in the light of dissections of fresh material from type localities My own types and those of Brauer and von Bergenstamm will have to be restudied in the same manner In fact, all accessible muscoid types the world over will have to be restudied in this new light Here is an amount of work to be done that almost staggers one to contemplate.

Brauer and von Bergenstamm possessed a most acute appreciation of the necessity for searching out even the most minute external characters in order to arrive at the true relationships of the forms They probably carried the study of the external adult characters about as far as it can be advantageously done without correlation with the reproductive and early-stage characters I have perhaps gone somewhat farther in my consideration of the external adult characters in the "Taxonomy of the Muscoidean Flies,"[4] but so far as I yet know without any great improvement in the general results It is thus evident that, for the future, the older order of taxonomic work in these groups must be exchanged for the newer one, which has come into full light but recently, and which demands the exhaustive study not only of the external and largely the internal characters of the adult, but also of the characters of the eggs and early stages. It may even greatly profit by a study of general bionomics, especially host relations

[4] "Smiths Misc Colls," No. 1803, May, 1908.

It is truly a most remarkable state of affairs that finds us at the present day unable to define some of the most common genera of tachinid flies Nevertheless, such is the fact and necessarily follows from what has here been said The type species of each genus must be dissected before we may know what species, themselves dissected, can be referred to that genus The material for such dissections should be fresh, and that for type dissections should be obtained from the type localities so far as possible I have already done this work for a considerable number of genera, and the results will, I hope, be published within the year accompanied by necessary drawings But hundreds of genera, many of them represented by names long in common use, remain to be investigated in this manner, and thus we frequently find ourselves at this late day unable to determine material in these groups with any hope of finality

In a recent letter to me, Dr John B Smith has restated the conditions in the following apt words, which I can not refrain from quoting:

> It is perhaps not surprising that in the Diptera, which are without any doubt physiologically the most highly developed of all orders, the difficulties in classification should be greatest Their specialization has extended in so many directions that the divergencies have become marked by internal modifications rather than external adaptations

He precedes these remarks by stating his belief "that it will require a study of the internal organs to get a satisfactory classification, which may afterwards be helped out by external characters whose importance is not recognized at the present time" This remark is well worthy of consideration. The correlation of the external adult characters with those of the reproductive system and early stages will define the relative taxonomic value of the first in the various groups, and may reveal unsuspected characters among them which will hold good for considerable series of groups.

The publication at this time of these remarks in their present form has been prompted by the recent appearance of Mr. W. R. Thompson's "Synonymical and other Notes on Diptera,"[4] which have just reached me and which I am extremely glad in this case to see published, since they are here serving the useful purpose of calling forth some timely observations that would otherwise have been reserved for the future. It is hardly possible that the synonymy indicated in the above-mentioned notes will eventually prove to be final. If so it will indicate the possession on the part of its author of most astute perception and perfect judgment of external adult characters, such as I myself can not lay claim to after more than twenty years' study of these flies. For the present, it certainly can not be accepted as such. No matter how carefully done or how clear one's perception, final synonymy in these groups can not be attained by the mere comparison of external anatomical parts in museum material, types or otherwise. It will henceforth be simply a waste of time, energy, paper and ink to put forth such results without correlation with the other characters mentioned, and I will therefore not discuss here the merits of the points raised in these notes, of most of which I have very serious doubt. But I shall return to these points as soon as I can secure proper material for the necessary dissections.

If students wish to further the interests and advance the status of muscoid taxonomy, let them collect, rear and dissect long series of specimens from the type localities concerned; they will then be in a position to deduce final synonymical conclusions. Any other course in the present stage of progress of the work will only further obscure the subject. The same ground will all have to be covered again and all raised or unraised points thoroughly probed to the bottom. In the study of these flies, no matter who agrees as to synonymy, whether generic or specific, if they have not done their work exhaustively their agreement is of slight interest to the matter in hand.

[4] *Psyche*, October, 1910.

The statement that I am going to make now will probably astonish some people, but I can truthfully say that I would be greatly pleased to see half the generic and specific names that have been proposed in the Muscoidea safely relegated to the synonymy where they could rest undisturbed and buried forever, with no hope of a resurrection, a goodly sprinkling of my own among the number, but such a considerable reduction of names is hardly possible of realization. Looking toward a consummation of final synonymy, however, I shall hope to accomplish in the next few years some portion of the work necessary to this end, during the course of which I here pledge my word that those generic and specific names of my own making will receive the same impartial treatment at my hands as all others. My one wish in this matter is to secure certainty before putting a name into the synonymy. The making of incorrect synonymy is a much more serious taxonomic offense than proposing further names for forms already named. In the latter case the forms can always be definitely referred to by means of the names that have been bestowed upon them, but in the former case serious confusion is certain to ensue.

The main interest here, as elsewhere in biology, centers in the relationships, phylogeny, bionomics and kindred aspects of the forms, and this knowledge must point the way to a sound taxonomy. In many groups of organisms this knowledge largely follows a fairly stable system of classification, but here it must precede it. It only remains to impress repeatedly upon the student the extreme difficulty at best of rightly interpreting the characters in such a multitude of forms, many of which are closely similar in the adult; the at least present impossibility in many cases of separating these forms on external adult characters alone; and therefore the absolute necessity for making an exhaustive study with reference to all taxonomically utilitarian characters, external and internal, of all stages.

Let no one think that I have over-estimated the needs of this subject in the foregoing remarks. I further wish to say, in conclusion,

that without doubt all biologists, myself included, will take great pleasure and satisfaction in welcoming to this field all careful workers, whose services should be much appreciated where there is such a vast amount of labor waiting to be performed

SPECIAL ARTICLES

METAMORPHOSIS WITHOUT PARASITISM IN THE UNIONIDÆ

IT has been known for a long time that in the genus *Strophitus* Rafinesque the embryos and glochidia are embedded in short cylindrical cords which are composed of a semi-translucent gelatinous substance, and that these cords, which are closely packed together, like chalk crayons in a box, lie transversely in the water-tubes of the marsupium The blunt ends of the cords are seen through the thin lamella of the outer gill, which in this genus, as in *Anodonta* and others, constitutes the marsupium The position of the masses of embryos, while contained within the gill, is so unusual that Simpson in his "Synopsis of the Naiades" established a special group, the Diagenæ, for *Strophitus*—the only genus of the family in which this peculiarity exists In other genera the embryos are conglutinated more or less closely to form flat plates or cylindrical masses, each one of which is contained in a separate water-tube and lies vertically in the marsupium

So far as we are aware, Isaac Lea[1] was the first to observe this interesting arrangement which he described and figured, rather crudely to be sure, in *Strophitus undulatus* (*Anodonta undulata*) In several subsequent communications[2] he added further details and illustrations, and also mentioned the occurrence of the transversely placed cords, or "sacks" as he called them, in *S. edentulus* He recorded the former species as being gravid from September until March, and described the extrusion of the cords from the female, as well as the remarkable emergence of the glochidia from the interior of the cords after the latter have been discharged "The sacks were discharged into the water by the parent," he says, "from day to day, for about a month in the middle of winter Eight or ten young were generally in each sack, but some were so short as only to have room for one or two . Immediately when the sacks came out from between the valves of the parent, most of the young were seen to be attached by the dorsal margin to the outer portion of the sack, as if it were a placenta"

The essential points in these observations have since been verified by other investigators Sterki,[3] following the suggestion of Lea, has called the cords, which differ strikingly from the conglutinated masses of *Unio* and other genera, "placentæ"—thus indicating that he considered them to have a nutritive function He also described the extrusion of the glochidia when placed in water, and their attachment to the cord "by a short byssus thread whose proximal end is attached to the soft parts of the young" He further states that the glochidia are enclosed in the placentæ when the latter are first discharged, and that after their extrusion they remain attached for some time

Ortmann,[4] in a paper on the breeding seasons of the Unionidæ of Pennsylvania, says of *S undulatus,* which he regards as identical with *edentulus*

> I found this species gravid in the months of July, August, September, October, also in May. The latest date is May 22, 1908 (one out of eleven individuals) Among numerous specimens collected on May 14 and May 27, 1908, no gravid females were present, and during the month of June such were never found, although a good number of specimens were collected The earliest date again is July 11 This gives an "interim" from the end of May to about the middle of July

In a later paper Ortmann[5] states that the discharge of the cords, which he proposes to

[1] "Observations on the Genus *Unio*," Vol II, 1838.

[2] *Ibid*, Vols. VI, X, 1858, 1863

[3] *Nautilus*, Vol XII, 1898.

[4] *Ibid*, Vol XXII, 1909

[5] *Ibid*, Vol XXIII, 1910.

call "placentulæ," is not through the lamellæ of the gills, as Simpson has maintained, but that it occurs in the usual manner through the suprabranchial chambers.

Strophitus edentulus is a rare species in all of the localities in which we have collected mussels, and we have obtained, until recently, only the following records of its breeding from individuals taken in the Mississippi River near La Crosse, Wis., during the summer of 1908.

Date	Number of Individuals	Stage of Gravidity
June 10	1	glochidia fully formed
July 6	1	glochidia fully formed
July 9	3	glochidia fully formed
July 10	1	glochidia fully formed
July 9	2	not gravid.
July 17	1	not gravid
July 18	2	not gravid
July 29	1	not gravid
July 29	4	young embryos
August 11	1	young embryos
August 11	3	late embryos

Since these records include the interim between the breeding seasons, they confirm the statement of Ortmann and others that *Strophitus edentulus* is one of the so-called "winter breeders," or those species which have the long period of gravidity. The interval between the seasons, however, as indicated in the above records, is seen to be a much shorter one than that observed by Ortmann.

After verifying the main observations of Lea and Sterki, so far as was possible at that season of the year, we examined the glochidia carefully with a view to determining whether their subsequent life-history would exhibit any peculiarities, as might be suspected from their relation to the cords. At that time we did not observe the normal discharge of the cords by the female; but we removed them from the marsupium, placed them in water, and, after the glochidia had emerged, employed various means to bring about their attachment to fish. None of these attempts, however, was successful, although the fish were left in small dishes containing many cords for as long a time as twelve hours. In the light of these results, which indicated the inability of this glochidium to attach itself to fish, and in view of the fact that the cords so evidently seemed to be a nutritive device, we felt it to be highly probable that in this species the metamorphosis would be found to occur in the absence of parasitism—a prediction which has been recently verified.

On February 6, 1911, a single female of *Strophitus edentulus*, which had been under observation in the laboratory since last November, was seen discharging its cords from the exhalent siphon. The discharge has continued to the present date, March 25, and during this time the cords have been thrown out in varying numbers from day to day. They measure from 2 to 10 mm. in length and about 1 mm. in diameter, although they become more or less swollen after lying in the water for a time. Each cord contains from 10 to 24 glochidia arranged in an irregular row. In many cases the glochidia emerge from the cords in a few minutes after the latter are discharged, and then usually remain attached by the thread in essentially the same manner as has been described by Lea and Sterki. The thread, which is apparently a modified larval thread, is continuous at its distal end with the egg-membrane, which generally remains embedded in the cord, so intimate, in fact, is the union between the two, that at times the membrane, adhering to the thread, is dragged out of the cord when the glochidium is extruded—in which case, of course, the glochidium becomes entirely detached from the cord.

All attempts to infect fish with these fully formed glochidia have again been unsuccessful, even when the exposure has been of long duration. Within a few days, the extruded glochidia die in spite of every effort to provide the most favorable conditions for their maintenance.

When the cords first began to be discharged, one of our students, Miss Daisy Young, happened to notice that not all of the larvæ were extruded, and that among those which remained in the cords some had lost the larval adductor muscle, possessed a protrusible foot, and showed other signs of having undergone the metamorphosis. Upon careful examina-

tion this was found to be true, and it was discovered that these young mussels—for such they undoubtedly are—are subsequently liberated by the disintegration of the cord after *having passed through the metamorphosis in the entire absence of a parasitic period* We, therefore, have concluded that the emergence from the cords in the glochidial stage is premature—due possibly to some change which has taken place in the gelatinous substance surrounding them as a result of free contact with the water or to release from the pressure to which they are subjected while in the marsupium It is perfectly evident that these glochidia neither become attached to fish nor undergo any further development, they have simply come out too soon and are lost

The young mussels, on the other hand, which have developed inside the cords, when liberated by the disintegration of the latter or removed directly by teasing, are found to have reached as advanced a stage of development as is attained by any unionid at the time it leaves the fish They closely resemble the young of *Anodonta* at the close of the parasitic period, and upon examination have been found to possess the following structures the anterior and posterior adductor muscles, the ciliated foot, two gill buds on each side, a completely differentiated digestive tract, including mouth, œsophagus, stomach, intestine and anus, liver, the cerebral, pedal and visceral ganglia, otocysts, the rudiments of the kidneys, heart and pericardium, and also a slight growth of the permanent shell around the margin of the shell of the glochidium. The larval muscle has completely disappeared, although some of the mantle-cells of the glochidium, as well as the hooks of the shell, are still present. They crawl slowly on the bottom of the dish by the characteristic jerking movements of the foot, after the manner of the young of other species at a corresponding stage, although the valves of the shell gape more widely apart and the foot is shorter and less extensible We have not succeeded as yet in keeping them alive for more than ten days, but it is difficult in the case of any species to maintain young mussels of this age under laboratory conditions.

Since these young mussels do not respond to the stimuli which cause glochidia to close the shell and all attempts to bring about their attachment to fish have failed, and, furthermore, since their behavior in creeping on the bottom is characteristic of post-parasitic life, it would seem clear that no subsequent parasitism is possible The conclusion is, therefore, inevitable that we have here to do with a species which has no parasitism in its life-history, although the presence of hooks and other typical glochidial structures would indicate that it has originated from ancestors which possessed the parasitic stage like other fresh-water mussels The cord is undoubtedly to be interpreted as a nutritive adaptation which arises in the marsupium during the early stages of gravidity, since the young embryos are at first contained in an unformed viscid matrix and the cords are a later product

The whole history of this exceptional species warrants a more detailed study, and Miss Young is now engaged in such an investigation When her work is completed, we hope that it may include the entire course of development, the method of formation of the cords, and the rearing of the young mussels during a much longer period than has thus far been possible

GEORGE LEFEVRE,
WINTERTON C CURTIS
UNIVERSITY OF MISSOURI,
March 25, 1911

THE SCALES OF THE ALBULID FISHES

Albula has long been regarded with unusual interest by ichthyologists, being an isolated type standing near the base of the Teleostean series It is exceptional among all teleosteans, Boulenger remarks, in having two transverse series of valves to the bulbus arteriosus instead of one, an approach to the condition of the "Ganoids," in which there are three. Gill admits the "Ganoids" into the teleostean series, and according to his arrangement *Amia* falls in the order Cycloganoidei, just before or below the Malacopterygii, of which *Albula* is a primitive member. In Smithsonian Misc. Coll., Vol 56, No 3, p. 2, I have

described the scales of *Albula*, showing that they have much in common with those of *Amia*, and are very different from those of *Elops*. The Albulidæ are evidently much nearer to the Cycloganoidei than are the Elopidæ, and if these two families stand side by side in the system, it must be understood that they are nevertheless quite far apart in fact. The striking feature of the scales in which *Albula* resembles *Amia* is the entirely longitudinal (instead of transverse) arrangement of the basal circuli, which in fact should be called *fibrillæ*. In *Amia* the nucleus is subapical, and the broad nuclear area is rugulose or covered with fine labyrinthiform markings. All this is seen in the living *Amia calva*, but even more beautifully in the Miocene *Amia scutata* Cope, scales of which I obtained at Florissant last month. Cope states that the scales of *A. scutata* are larger than those of *A. calva*, but I find them to be practically of the same size, with very strong longitudinal fibrillæ, fraying out basally, and a most beautiful and intricate labyrinthiform sculpture in the broad nuclear area. This labyrinthiform condition of the nuclear area is not uncommon among the lower groups of teleosteans in the stricter sense, and is variably developed in *Elops*. In the characinid *Prochilodus rubrotæniatus* Schomb. the transition from the rugose or labyrinthiform nuclear area to the regularly circulate type is curiously shown, the area becoming multinucleate, with several small "islands" surrounded by circuli. *Albula vulpes* has large subquadrate scales, with about three basal radii, leading to deep emarginations of the base, which therein departs markedly from *Amia* and resembles the normal condition of many higher Teleosts. The subapical region is rugulose, very much as in *Amia*, but the true nucleus, just below it, is surrounded by fine regular circuli. It is in this small central region, above the nucleus, that *Albula* has genuinely transverse (concentric) circuli. It is also to be remarked that the basal circuli are all beaded in *Albula*, whereby they differ from *Amia*, but agree with the Osteoglossidæ.

Strong new interest in the Albulidæ has been aroused by the description of a new genus by Mr. Henry W. Fowler in *Proc. Acad. Nat. Sci. Philadelphia*, LXII (1911), p. 651. This very interesting fish, *Dixonina nemoptera*, was found mixed with specimens of *Albula* from Santo Domingo, collected long ago by Gabb. Fowler writes of the scales that they are "cycloid, inner edges mostly crimped, outer or exposed edges thin or membranous and ragged, marked submarginally with a concurrent vertical ridge or striation, the true edge of the scale." I am greatly indebted to Dr. D. S. Jordan for an opportunity to study a couple of scales of *Dixonina nemoptera*, taken from the original type. They are about 8.5 mm. broad and long, and in structure agree perfectly with those of *Albula*. The nucleus with its concentric circuli, the beaded longitudinal basal circuli, the three basal radii and three basal emarginations, etc., are all the same. The dermal pigment spots also agree. In some ways this exact correspondence is rather disappointing, but it shows the conservative nature of the scale-pattern, and rather emphasizes its value as diagnostic not merely of the genus *Albula*, but of the group to which it belongs.

T. D. A. COCKERELL

UNIVERSITY OF COLORADO,
BOULDER, COLO.

THE SIGNIFICANCE OF LEAD ARSENATE COMPOSITION

THE control of a large class of the insect pests of growing crops depends on the use of arsenical sprays, and the commercial importance of such spraying has assumed very large proportions in recent years. Two factors determine the limits to which such methods may be carried with success. The first factor is the amount, character and timing of the applications necessary to control the insect. The second factor is the degree of toleration for the spraying treatments which the crop in question may possess. It is with the latter part of the problem that the following discussion is concerned.

Arsenic may injure plants quite as seriously as animal tissue, and the efforts of investigators have been directed towards preventing

the absorption of the arsenical by the sprayed plants It is assumed that solid bodies can not penetrate the epidermis of healthy plants, but the absorption of liquids is known to take place Nothing has developed to show that the first premise is unsound, and the question may well be asked, why have many of the arsenical compounds designated as insoluble by chemists, proved to be injurious when applied as sprays? The most obvious answer is found in the supposition that these compounds are not insoluble under the conditions of the application

Solubility implies a solvent, and the most universally present solvent found in nature is water Chemists base their estimates on solubility in pure water, and on the results of comparatively short exposures to this solvent On the other hand, natural water may not be pure, and under some climatic conditions the exposure of spray deposits, on plants, to the action of natural water may be very prolonged

It is very important to note that the last implied condition, that of prolonged exposure of the spray deposit to moisture, is one which prevails to a great extent in the Pajaro Valley, California This valley is situated near the coast, about one hundred miles south of San Francisco, and opens out onto the ocean The apple orchards of the locality have exhibited a remarkable susceptibility to arsenical injury, and to such an extent as to seriously interfere with effective control of the codling moth by the use of arsenic compounds The industry is a large one, as the production has averaged over three thousand cars annually for the last ten years. An industry of such proportions was deserving of considerable attention from those delegated to foster the horticultural interests of the state, and the university experiment station has properly responded to the demand.

Field and laboratory work was commenced in the spring of 1908, and the author became connected with the investigation in the fall of that year Since that date the work has gone on continuously, and largely under the writer's supervision.

That the results have been satisfactory, is reflected by the methods of spraying and materials used by the growers at the present time The influence of this investigation is also apparent in the orchard practise of the entire Pacific coast and many of the interior states, but comparatively little publication has been done Now that the attention of many investigators is being attracted to arsenical injury and kindred problems it appears that the results of our work should be properly published With this end in view, the author has recently issued a circular entitled "Foliage Testing of Arsenicals" In the present article it is intended to cover in more detail the purely chemical considerations.

To continue with water solubility; the climatic conditions of the Pajaro Valley are peculiar in that there is a large amount of fog and dew moisture through the spring and summer months The foliage of the trees becomes wet early in the evening and remains so during the night and well into the following morning This condition may continue without interruption for a period of several weeks The dew and fog moisture may at times be abundant enough to drip liberally from the trees, but more often it is nearly all retained on the foliage where it evaporates during the following forenoon Such conditions are evidently ideal for dissolving substances on the leaves, and for the absorption of the solutions by the plant tissues As contrasted with rains which wash dissolved substances entirely away, the above-described conditions are much more trying, and partly explain why apple foliage in the eastern states has been so little subject to arsenical injury.

With regard to the action of substances in solution in the water used to suspend arsenical compounds, when applied as a spray, Haywood and McDonnell[1] and others have shown that chlorides, carbonates and sulphates render the arsenic oxide in certain varieties of arsenate of lead more soluble and increase the danger of foliage injury. On the other hand, we have found that distilled water does not

[1] U S Dept. of Agr, Bureau of Chemistry, Bul 131, p 46

eliminate the injury, but may prolong the time required for it to take place. Also, arsenicals of several types, applied as dust sprays (without water), have produced injury under our climatic conditions. At the same time and under the same conditions arsenicals have been applied that produced no injury or a very small amount. Such variation from perfect foliage neutrality to serious injury was found in a series of arsenate of lead samples. The samples which produced no injury were found to still retain their non-injurious properties when mixed up for spraying in any of the various waters in common use in the locality. These waters vary from 40 to 150 parts per 100,000 of salts in solution, chlorides, carbonates and sulphates forming the bulk of the salts.

Thus, all degrees of injury were obtained when samples of that material commonly known as arsenate of lead were applied to foliage with the same water. Such results indicated a radical difference in the chemical properties of the various samples. Chemical authorities mention several plumbic arsenates, but consider them as being alike insoluble in water. However, "Handbuch der Anorganischen Chemie" (O. Dammer), Vol. 11, Part 2, pp. 565 and 566, states that pyro-arsenate ($Pb_2As_2O_7$) is soluble in ammonia while the ortho-arsenate [$Pb_3(AsO_4)_2$] is not. This brief statement requires interpretation and may be expanded as follows:[3] The acid arsenates are stable under acid conditions, but are transposed into the ortho-arsenate, the most stable compound, under neutral and alkalin conditions. This transposition involves the liberation of arsenic oxide or soluble arsenates. The significance is at once apparent. When arsenate of lead is applied as a spray it is subjected to neutral and alkalin conditions. This is especially true if the water used in spraying contains alkalies. That is, the conditions favorable to transposition of the acid arsenates into the ortho-compound obtain. As fast as the neutral waters of fogs, dews and rains wash away the liberated arsenic oxide, or when the latter is absorbed by the plant tissues themselves, the conditions are restored for more to be formed. The ultimate result is the complete transposition of the acid arsenates to the ortho-compound and the liberation of the excess arsenic oxide.

At the time when these conclusions were reached we had the records of a large number of foliage tests with arsenate of lead samples. Checking these off showed that without exception those simple plumbic arsenates which produced no injury contained lead oxide and arsenic oxide in the correct proportions to produce the ortho-arsenate.

These results were obtained in 1906 and in the early part of 1907, and while the evidence was then sufficient to exclude practically all doubt, it was thought best to wait until several years of commercial spraying and supplementary experimental work should give incontestable grounds to announce the deductions as fully supported by experimental evidence.

To continue further with deductions which are probably correct. Some authors recognize pyro-arsenate ($Pb_2As_2O_7$) and others only hydrogen-arsenate ($PbHAsO_4$) as occurring in wet precipitates. Our results apparently show that both compounds may occur in commercial lead arsenate. Foliage tests show that pure hydrogen-arsenate behaves differently from mixtures containing considerable proportions of the ortho-arsenate. These mixtures of ortho and pyro are more rapidly injurious than the pure hydrogen-arsenate.

A chemical explanation of this fact is apparent. Lead-hydrogen-arsenate is $Pb_2As_2O_7$ to which one molecule of water has been added, that is, $Pb_2As_2O_7 + H_2O = (PbHAsO_4)_2$. In other words, $PbHAsO_4$ is a product of the hydrolysis of $Pb_2As_2O_7$. The H_2O may even be regarded as water of crystallization as the hydrogen-arsenate is crystalline rather than amorphous in structure. This rearrangement of the molecule gives opportunity for rapid transposition to the ortho-arsenate, and would

[3] The credit for this interpretation belongs to Mr. E. E. Luther, at that time (1906) an assistant in the laboratory at Watsonville. This discovery not only explained the injurious properties of certain types of lead arsenate, but also indicated the means by which such injury could be overcome.

explain the more rapid injury from samples containing unhydrolized pyro-arsenate.

The Ammonia Test.—The reaction between ammonia water and the acid arsenates of lead may be used to test the presence of these compounds in a sample.

A fair-sized sample (10 to 20 grams) is worked up in water (25 to 50 c.c.) and an equal volume of strong ammonia (26° B.) is added. This is digested with heat, agitated and finally brought to the boiling point. The sample is then allowed to cool and settle, and the clear solution decanted through a filter. The filtrate is boiled until the ammonia is nearly or all driven off. The remaining solution is then made distinctly acid with acetic acid, and a concentrated solution of lead acetate containing free acetic acid is added. Any arsenic acid which the filtrate may carry will then be precipitated in the form of acid arsenate of lead. With no precipitate forming at first, add the lead acetate solution to large excess and allow to stand. A preciptate may appear in a few minutes or an hour.

With this treatment pyro-arsenate, hydrogen-arsenate and mixtures of ortho and pyro give abundant white precipitates. In any case where the precipitate forms at once and can be designated as more than a trace, *i. e.*, renders the filtrate opaque, the sample will prove injurious under foliage test conditions, and will probably prove injurious in commercial spraying operations, especially where climatic conditions favor such injury. On the other hand, samples which show no ammonia test are practically free from foliage-injuring properties.

The ammonia reaction is complete and may be used for the quantitative determination of any arsenic oxide that may be present in excess of that required to form the ortho-compound.

Errors arising from Chemical Tests and Analysis.—It is not enough to know that the ratio of As_2O_5 to PbO is as 1 to 2.90 or more. The essential thing is whether all the PbO is combined with the As_2O_5. Chlorine and organic bodies may retain sufficient lead to materially affect the nature of the compound. In case the arsenic oxide content is slightly greater than it should be, and an estimable quantity of chlorine is present, the sample will certainly give an ammonia test and prove injurious to foliage under test conditions.

The true ortho samples will probably show an excess of lead oxide amounting to 1 to 4 per cent.

The ammonia test is positive except in rare cases where the uncombined lead is sufficient to take up the liberated arsenic oxide.

Water Solubility.—This subject has received much attention from chemists but as usually handled, does not indicate the true condition of the sample. Most arsenicals yield only a limited portion of their arsenic to a given amount of water, but may repeat this a very great number of times. As has already been shown, the liberation of arsenic oxide from the acid arsenates depends on transposition to ortho under neutral and alkalin conditions. However, the amount of arsenic acid taken up by a given volume of water can not exceed a very small quantity before the reaction of the solvent becomes acid and stops the transposition. As a matter of fact, such solutions are neutral or alkalin to litmus.

The water solubility of arsenate of lead is readily shown in a qualitative way by digesting in water for a time (ten to twenty-four hours), decanting through a filter, acidifying the filtrate with acetic acid and then adding lead acetate solution as in the ammonia test. A white precipitate or turbidity indicates water-soluble arsenic oxide. This operation should be repeated a number of times to determine whether the amount of dissolved arsenic oxide remains a constant. With this method of treatment ortho- and acid-arsenate samples show a decided difference in behavior. Both arsenates may show about the same arsenic oxide content per unit volume of water for the first two or three washings. After that, however, the quantity of arsenic removed from the ortho sample will be very much reduced, but that from the acid sample will remain practically constant for a large number of washings. A device by which a con-

stant stream of pure water could be run through the sample and collected for evaporation to a suitable volume would likely be the best method for determining relative water solubility.

Laboratory Preparation of Lead Ortho-arsenate.—Very few American chemists appear to have experimented with the ortho-arsenate of lead. Probably this is due to the fact that the formulas most often published do not produce this compound in the pure state, that is unmixed with acid arsenates. True ortho-arsenate may be prepared as follows.

Solutions of lead acetate or nitrate and arsenic acid or ammonium, sodium or potassium arsenate containing the correct weights of the oxides (1 part of As_2O_5 to 2.90 PbO) are poured together. The water should be sufficient to dilute the precipitate so that it will not form too thick a mass. To this mixture ammonia is added to strong alkalinity. The mixture is digested with gentle heat for an hour or more, allowed to settle, and the clear liquid tested for arsenic oxide as described under the ammonia test. If a precipitate forms, a little more lead solution is added and the procedure repeated until no precipitate appears. It is well to wash the finished product and again treat with ammonia. If any arsenic oxide appears in the filtrate more lead solution should be added. Finally wash to the complete removal of water-soluble salts. In accordance with well-known principles of chemistry the retention of the arsenic oxide will not be complete until there is an excess of the precipitant, that is, lead oxide. For this reason true ortho samples will show less than the theoretical percentage of arsenic oxide (25.59 per cent.). With commercial samples, where allowance has to be made for impurities, this percentage is still further reduced.

It appears, then, that the federal insecticide and fungicide law rules out commercial ortho-arsenate of lead prepared on a 50-per-cent. water basis, by requiring 12.5 per cent. arsenic oxide. The manufacturers may still comply with the law by reducing the water percentage, but this is done at expense of easy remixing, so working a hardship on the consumer. It is my opinion that this clause in the act should be amended to read: "In the case of strictly ortho-arsenate of lead, the arsenic oxide content shall not be less than 11 per cent. or more than 12.5 per cent. on a 50-per-cent. water basis."

Further Discussion of Water.—Haywood, as already cited, has shown that chlorides, carbonates and sulphates may seriously increase arsenical injury from acid and pyro-ortho mixtures even when present in comparatively small amounts. Some recent results with these arsenates in commercial spraying apparently bear out such conclusions. The commercial ortho-arsenate usually contains enough excess lead oxide to offset these effects, but cases can be imagined where this compound might be partly decomposed. In such instances it is clearly possible to overcome the difficulty by treating the water with lead acetate. The addition of lead acetate until the water shows a reaction for soluble lead should give the desired result. The presence of small amounts of lead acetate will not prove injurious, and we have applied the carbonate and sulphate in very large quantities without producing the slightest injury. Lead acetate will completely overcome the effects of carbonates and sulphates and should greatly reduce the solvent action of chlorides.

Acknowledgments.—The investigations of which the features of this discussion form a part have had a wide scope and important contributions have been made by several people, among whom may be mentioned Professors C. W. Woodworth, W. T. Clarke, Geo. E. Colby and Mr. E. E. Luther.

SOCIETIES AND ACADEMIES

THE WASHINGTON ACADEMY OF SCIENCES

The Washington Academy of Sciences held its 71st meeting in the auditorium of the New National Museum on the evening of April 18, 1911. President F. W. Clarke presided.

Sir John Murray, of Scotland, gave a most interesting and beautifully illustrated lecture on "The Ocean."

Maps were shown that gave the depths of the several oceans, the directions of their currents, their temperatures at all depths, their salinity, density and other physical conditions The importance of each of these phenomena was clearly stated and their interdependence carefully explained It was explained, for instance, that life at considerable depths in the sea is dependent upon vertical circulation, because in this way only is it possible to bring to the lower portions the necessary amount of oxygen This explains the absence of life in the deeper portions of the Black Sea in which the distribution of density is such that it produces horizontal currents only

Even those portions of the ocean farthest removed from land have an abundance of animal life, which in the last analysis must live upon vegetable matter But this, the lecturer explained, is everywhere present in such abundance, though consisting of microscopic individuals, that the oceans may be thought of as vast meadows containing even more vegetable matter than is upon the land

A most interesting and possibly important fact is the change, after a lapse of a few years, in the temperature of the deeper layers of the sargasso sea These temperatures should be taken several times a year for a number of years, for the purpose of determining whether the change is cyclic, and what its causes and its consequences are

These are only some of the topics discussed in a lecture that combined in the highest degree the interesting and the instructive

THE 70th meeting of the Washington Academy of Sciences was held in the assembly room of the Cosmos Club at 8 15 P M, March 30, 1911 President F W Clarke presided

Professor Dr. Victor Goldschmidt, professor of mineralogy in the University of Heidelberg, Germany, presented a paper on "The Nature of Crystals"

The lecturer began with humorous descriptions of school day experiences when we studied crystallography by the aid of painted wooden and pasteboard models, and from them got the idea that real crystals were mighty poor imitations of our beautiful wooden blocks

By way of emphasizing the importance of the subject of crystallography it was stated that all ice and snow, all rocks whether of mountains or in the deep strata of plains, the moon, wandering meteors and all solids from liquids, are crystals

A philosophical and all-comprehensive definition of crystals was then developed, and contrasted with the similar definition of a liquid A crystal was defined as being "A solid system of like particles with like orientation" A liquid was defined as "A system of gliding and rotating particles"

Any one who thinks crystallography either an unworthy or uninteresting subject is very much mistaken, Dr Goldschmidt declared, and by his lecture, in the opinion of all who heard him, made good this claim

W J HUMPHREYS,
Secretary

THE BOTANICAL SOCIETY OF WASHINGTON

THE 73d regular meeting of the society was held at the Cosmos Club, Tuesday, May 2, 1911, at eight o'clock P M President W J Spillman presided Thirty one members were present

Mr Walter T Swingle presented a review of a recent paper by de Vries entitled "Ueber doppeltreziproke Bastarde von *Œnothera biennis* L und *O muricata* L," in *Biologisches Centralblatt*, 31 97-104, No 4, February 15, 1911 This review will appear in full in SCIENCE

The following papers were read

The Recent Excursion into the Dismal Swamp F V COVILLE

After describing an excursion made by the Washington Academy of Sciences into the Dismal Swamp of Virginia, April 28-30, 1911, the author discussed the characteristic plant associations of the Dismal Swamp which are those of the "black gum" and the "juniper" areas, the latter being of unusual ecological interest

The "juniper" lands of the Dismal Swamp have a special flora different from the other floras of the region The characteristic tree is the southern white cedar (*Chamæcyparis thyoides*), locally known as "juniper" The common shrubs are swamp blueberry (*Vaccinium corymbosum*), white alder (*Clethra alnifolia*), inkberry (*Ilex glabra*), fetterbush (*Pieris nitida*), and various other species belonging to the heather family. The soil is a red brown peat, made up of the dead roots, twigs and leaves of the swamp vegetation The water of these juniper swamps contains a remarkably small quantity of mineral matter, and has the color of tea, due to a dilute solution of organic matter derived from the peat When tested with phenolphthalein the water gives an acid reaction, to the degree of .0005 of a normal acid solution The peculiar flora of the juniper swamp

is attributed to the acidity of this water and of the peat from which it flows, the chemical qualities of the water preventing the growth of the organisms of decay, and preserving the soil in such a condition of acidity as to make it impossible for ordinary swamp plants to grow on these lands. The "juniper" trees and other vegetation of these areas are specially resistant to acidity and are able to grow with luxuriance in such a situation. The antiseptic quality of this water is further attested by the estimation in which it has long been held among sailors for drinking purposes. Before the days of distilled sea water, the favorite water supply of ships leaving Norfolk on a long voyage was "juniper" water from the Dismal Swamp. No other water was so highly esteemed and none kept its sweetness so well.

The Effect of the Reaction of Solutions on the Growth of Wheat Seedlings: J. F. BREAZEALE and J. A. LE CLERC. (Read by Dr. Le Clerc.)

The authors showed, by the use of lantern slides of photographs of seedlings grown in various solutions, that the development of the roots of the seedlings was injuriously affected by all the solutions that had become appreciably acid in reaction. This acid reaction was most marked with the application of KCl and K_2SO_4, the plant exerting a selective action for the K ion, thus leaving the acid radicle Cl or SO_4 behind, which in turn made the culture medium acid by which the growth of the roots was stunted. The conclusion was drawn that the reaction of the solution played a most important rôle in the development of the seedlings.

Some Changes which take Place in Stored Grain: DR. J. W. T. DUVEL.

This paper treated mainly of the more important changes which take place in commercial corn during storage in grain elevators and holds of steamships. Corn thus stored frequently contains relatively high percentages of moisture, thus affording an excellent opportunity for the development of molds and bacteria. The development of these organisms, together with the action of unorganized ferments, is accompanied by a distinct and rapid increase in temperature and a marked deterioration in the grain. Such grain is known commercially as "heating" or "hot" and after it starts to go "out of condition" it usually reaches a temperature of from 135° to 150° F. within a very few days. The viability is greatly reduced or entirely destroyed, and there is a marked increase in the acidity, a reduction in the percentage of both sucrose and invert sugar, and a considerable loss in fat. Other important changes also occur in the chemical composition of the grain, together with a heavy loss in weight and a lowering in the weight per bushel.

W. W. STOCKBERGER,
Corresponding Secretary

THE ASSOCIATION OF TEACHERS OF MATHEMATICS IN THE MIDDLE STATES AND MARYLAND

THE sixteenth meeting of the association was held in Teachers College, New York, April 22, 1911. The meeting was called to order by the president, Dr. Wm. H. Metzler, at 10.30 A.M. in the chapel of the college.

After the reading of the minutes, Mr. Breckenridge, chairman of the committee on continuation schools, reported the progress of his committee. The report was very interesting in the matter of the attitude of the students in those schools for more pure mathematics, merely because of their place in the curriculum of the ordinary day school. The report was accepted and the committee was continued. The algebra syllabus committee was also continued.

The first paper of the morning was given by J. S. Rorer, of the Wm. Penn High School, Philadelphia, on "The Curriculum: Present Tendencies, Future Possibilities."

The work of the morning was concluded by a paper by A. M. Curtis, of the Oneonta Normal School, on "Study Supervision: Its Needs in the Mathematics of the Elementary and Secondary Schools."

The first paper of the afternoon was a description, with lecture table models, of the slide rule and its uses, by Clifford B. Upton, of Teachers College. This was followed by a description, with stereopticon illustrations, of the calculating machines then on exhibition in the educational museum of Teachers College.

Preliminary reports for the committees on arithmetic, algebra and geometry were given by Mr. Rorer for the committee on arithmetic and by Mr. Durrell for the committee on geometry. These reports consisted of plans for carrying on the work.

After expressing its thanks to Teachers College the meeting adjourned to the educational museum for the privilege of inspecting the exhibition of slide rules, calculating machines, rare books and manuscripts.

H. F. HART,
Secretary

ALEXANDER AGASSIZ: HIS LIFE AND SCIENTIFIC WORK[1]

ALEXANDER AGASSIZ, our distinguished alumnus and my friend, died at sea in mid-ocean on board the S. S. *Adriatic* on Easter morning, March 27, 1910. When this information was received in England by wireless message, it was believed that some mistake had been made, for only a few days previously he had parted with scientific friends in London apparently in most excellent health. The sad news was too speedily confirmed. A few days later I had occasion to speak before an assemblage of scientific men and oceanographers, and I said his death was a great loss to American science, to the science of oceanography, and to all people who take an interest in the progress of natural knowledge. On this occasion I propose to show that this statement was fully justified, and that a truly great man passed from the world when Alexander Agassiz died.

Alexander Agassiz was the only son of the famous naturalist, Louis Agassiz, by his first wife, Cecile Braun, and was born at Neuchâtel in Switzerland on December 17, 1835. His school days were spent at his birthplace and at the Burger School at Freiburg, in Baden, Germany, where his maternal uncle was a professor in the university, where his mother and sisters then resided, and where he also came under the influence of a great biologist, Professor Theo. von Siebold. Here were laid the foundations of an education in the French

[1] Memorial address delivered in Sanders Theater, Cambridge, Mass., March 22, 1911, at the request of the president and fellows of Harvard College. Reprinted from the Bulletin of the Museum of Comparative Zoology at Harvard College.

and German languages and in science, which proved a great advantage in his future career His mother was an artist, and we have hints that her temperament was very different from the placid uniformity which is said to have been characteristic of his father The father and son are said by Dr Walcott, who knew them both well, to have apparently belonged to absolutely different types[2] When I sometimes observed outbursts of indignation, and impatience in Alexander Agassiz, I was always reminded of a passage in the quarrel between Cassius and Brutus in the play of Julius Cæsar

Cassius exclaims

Have you not love enough to bear with me,
When that rash humor which my mother gave me
Makes me forgetful?

And Brutus replies,

Yes, Cassius, and from henceforth,
When you are over-earnest with your Brutus,
He'll think your mother chides, and leave you so

In 1849, at the age of thirteen years, the young Agassiz joined his father in America, and his later education took place at Harvard College and the Lawrence Scientific School at Cambridge, Mass, where the elder Agassiz occupied the chair of natural history. He used to refer with much pleasure and satisfaction to the manner in which he was befriended, soon after his arrival in the country, by Augustus Lowell, the father of our President Lowell In 1855 Alexander Agassiz graduated at Harvard Two years later he took the degree of S B. in civil engineering, and later a second S B degree in natural history Between 1856 and 1859 he taught in the Agassiz School, and here it was he first met, as a pupil, the young lady who was to become his wife In 1859 he was appointed an assistant in the United States Coast Survey, and worked in California and Washington Territory

[2] *Boston Evening Transcript*, April 6, 1910.

In 1860, at the age of twenty-six, he married Anna Russell It was a love match, and the young couple started out with a very slender income. In the same year Agassiz was appointed assistant zoologist in the Museum of Comparative Zoology at Cambridge, founded by his father His connection with this institution lasted as long as he lived—a full half century During half of that period he acted as curator, succeeding his father On resigning the curatorship in September, 1898, he served on the faculty of the museum as secretary In 1902 he was made director of the University Museum

In 1863 Agassiz became interested in coal mining in Pennsylvania, but afterwards turned his attention to the copper mines of Lake Superior, acting as superintendent of the Calumet and Hecla mines from March, 1867, to October, 1868 It was in consequence of his ability, attention, devotion and business habits that these mines turned out a great financial success at a later date Up to the time of his death he was president of this successful company

In 1869 he had a severe illness at Cambridge from the effects of over-work, anxiety and exposure at Calumet, from which it is believed he never fully recovered. The years immediately preceding this illness had been full of all the financial and other worries connected with mine superintendence and the care of a large and growing business. Still even at this busy period we find the dominant note of Alexander Agassiz's life continuously sounded—the desire to add to the sum of natural knowledge

As a boy he had accompanied his father on his cruise in the *Bibb* off Nantucket, and in 1851 he aided in the survey of the Florida Reefs. Before he had reached the age of thirty over twenty publications had

appeared from his pen in various American scientific journals, the subjects ranging from the flight of lepidoptera and beaver dams to the position of sandstones on the shores of Lake Superior, and zoological classification.

The great majority, however, of these papers deal with marine organisms, such as medusæ, salpæ, annelids, actinæ, echinoderms and various pelagic larvæ. These papers, as well as the fact that he published in 1865, conjointly with his stepmother, Mrs. E. C. Agassiz, a popular book on marine life entitled "Seaside Studies in Natural History," show that even in his early career he was fascinated by the ocean, its myriad inhabitants and their conditions of existence. It could not well be otherwise, considering the intellectual atmosphere by which he was surrounded. He took a keen interest in the explorations of his friend, Pourtalès, off the coasts of Florida, and assisted in the description of his collections. In fact Agassiz's early manhood coincided with the great renewal of interest in the physical and biological conditions of the great ocean basins. Maury and Brooke had taught men how to sound correctly the deep sea, and Maury had published his "Physical Geography of the Sea" and a depth chart of the whole North Atlantic. Bailey had examined microscopically the deep-sea deposits under the gulf stream; Pourtalès had discussed the formation of green-sand in the same deposits, and the older Agassiz had pointed out the bearing of these new facts on the question of the permanence of continents and ocean basins. The observations of Lovén and Michael Sars had shown that, if there was a zero of life in the great oceans, it must lie at a much greater depth than Forbes had indicated from his observations in the Mediterranean. Wallich, Huxley and Haeckel had expounded their views on the habitat of the Globigerinæ, the shells of which covered the floor of the ocean, and of some organisms brought up from a great depth on sounding lines. The renowned "Bathybius" had been described as a living carpet on the ocean-floor and was accepted by the scientific world. Wyville Thomson, Jeffreys and Carpenter had conducted deep-sea explorations in the *Lightning*, *Porcupine* and *Shearwater*, capturing in great depths crinoids, irregular sea urchins and other marine creatures which were reminiscent of fossil forms.

All these fresh and striking facts, and the speculations connected therewith, must have been present in the mind of the young naturalist when recovering from his severe illness in 1869. One can well imagine how earnestly he desired to take an active part in the new explorations and investigations which were either then being carried out or were projected for the near future. At this time an unexpected occurrence enabled him to realize a long wished-for opportunity of visiting and examining the echini collections in European museums and of becoming personally acquainted with the British naturalists then engaged in oceanographical work and deep-sea exploration. One day when recovering from his illness he chanced to meet his friend, Mr. James Lawrence, of Boston. Lawrence remarked, "How ill you are looking!" and Agassiz replied that he thought he was dying. "Nonsense," said Lawrence, "what you need is rest and change of scene." "I can not afford it," was the reply. "Oh yes! you can," said Lawrence, "I'll be your banker." Agassiz never referred to this incident without emotion. He always felt that he owed his life to Mr. Lawrence.

Mr. and Mrs. Agassiz sailed for Europe in the autumn of 1869, with their children

and were absent from Boston for fully a year. This was a period of convalescence and of great pleasure and enjoyment; it was also a period of great activity and hard work. His first visit was to Wyville Thomson, who was then professor at Belfast, in Ireland. Years previously they had been in correspondence about the distribution and development of echinoderms, and Agassiz was, of course, anxious to see him and to learn all about the *Lightning* and *Porcupine* expeditions, in which Wyville Thomson had taken part, and concerning which he had just published a statement of results. The subsequent correspondence shows that this, as well as another visit towards the end of 1870, gave the greatest satisfaction to both naturalists as well as to their wives. Agassiz then proceeded to visit and examine the echini collections in nearly every museum in Europe. The great majority of the original type specimens described by the principal writers on the subject during the nineteeth century thus passed through his hands and were critically compared with specimens from the Museum of Comparative Zoology in Cambridge and from the recent deep-sea expeditions. A few extracts from his own letters will best indicate his progress, occupations and impressions during this visit to Europe.

Wyville Thomson had written to Agassiz after his visit to Belfast that he had lost or mislaid some deep-sea specimen, and Agassiz, jocularly, replied from London, assuring him that he had "taken nothing away from Ireland except a bad cold."

From Copenhagen he writes to Wyville Thomson: "What a pleasant place this is! My wife wishes me to send her kindest regards to Mrs. Thomson and yourself. I am here after a most successful trip through Germany, and am on my way to Stockholm. By the time I get through, we shall have been in every place where there is anything to be seen in the way of type echinoderms. I am getting on famously as far as the material for the echini catalogue is concerned. In Berlin I saw many nice things from Japan. I am just finishing the echinoids here with Lutken, who is a most charming fellow. . . ."

From Switzerland (Leuk, August 8, 1870) he writes: "I have done now with my examination of the Echini collections, having now seen them all, and I hope I shall not be prevented from getting out my catalogue very rapidly after my return home."

From Lausanne (August 23, 1870) he again writes to Wyville Thomson: "We have just come back from a charming trip to the mountains, had pleasant weather the whole time, besides doing us all a great deal of good. I am happy to say I am now picking up fast, and if I keep up at the present rate trust to be perfectly well this fall when I go home. We hope to be in London last part of October. We sail 8th November, and I shall manage if possible to take a run to Belfast and see what you have got (that is from the *Porcupine* expedition). . . . I hope you will have the best of luck on your new trip, and find something more astounding than Rhizocrinus, Pourtalèsia or Calveria. Mrs. Agassiz wishes me to thank you very much for your kind invitation, and to send her kindest remembrances to yourself and Mrs. Thomson."

Here are some extracts from his letters immediately after his arrival at home:

"We had a capital passage, except two days when it was rough, it was quite pleasant, the whole not lasting more than a little over eight days from Queenstown, which for the season was admirable. I found father much better than I had hoped

to see him again. He manages to come to the museum for an hour or so a day, sees a few of his friends every day, and keeps going just enough to be employed He improves daily, and I see no reason why he should not have a long period of usefulness yet, though of course nothing like his old work can now be expected from him again "

In March, 1871, he writes (from Cambridge)—"I am just getting out a new edition of the Seaside Studies, which will, however, be a mere reprint"—and in March, 1872 "I hope you will accept the offer to go round the globe, and if you go may you get all the antediluvial things left I am greatly afraid father's expedition is not going to result as well as we hoped, the vessel is a great disappointment, five weeks out of ten they have spent repairing They have left Rio, and the next mail trust to hear from them in the Straits of Magellan "

In April, 1872, he says "Don't be alarmed by the number of my epistles But I wanted to acknowledge at once the safe arrival of the 'Calveria' and of the 'Phormosoma' I need not tell you how greatly obliged I am to you . "

The "Revision of the Echini"[8] began to appear the year after his return from Europe This is the best known of the works of Alexander Agassiz and at once stamped the writer as the leading authority on the subject Part I. deals with the literature, nomenclature, synonymy and geographical distribution of the echini, and extends to 242 pages. Part II. deals with the echini of the east coast of the United States, including a report on the deep-sea echini collected in the Straits of Florida by Pourtalès in 1867–1869, and extends to 136 pages Part III contains the descriptions of the species of recent echini, and extends to 251 pages Part IV deals with the structure and embryology of the echini, and extends to 141 pages The text thus occupies 770 quarto pages, and is illustrated by seven maps showing the geographical distribution and 87 plates giving full figures and details, in addition to numerous wood-cuts in the text This report represents an immense amount of work and close study, and it became the standard for all subsequent investigations dealing with this class of animals

Agassiz throughout his active scientific life was a constant student of echinoderms He worked on starfishes and crinoids, but the principal object of his interest was the recent echini His first publication on this fascinating group of animals was in 1863, and his last in 1909, covering a term of forty-six years, a long period of sustained interest and work. He described a considerable part of the deep-sea species and genera known to science in his monographs on the deep-sea echini collected by the *Challenger*, *Blake* and *Albatross* expeditions He described as new, about one third of the known recent echini, of which there are some 450 species

In addition to systematic work, he published on the development and morphology of echini as well as on their geographical and bathymetrical distribution His work was almost wholly on recent forms, but in several of his works, especially the revision, and *Challenger* report, there is discussion of, and some observations on, fossil echini.

The three years immediately succeeding his return from Europe in December,

[8] "Revision of the Echini," Illustr Cat. Mus Comp. Zool. (Cambridge, Mass), No VII, 1872–1874, by Alexander Agassiz. It was divided into four parts for purposes of publication; Parts I. and II. were issued together in 1872, the introduction being dated August, 1872, Part III. in September, 1873, and Part IV. in January, 1874.

1870, were the most active, fruitful and enjoyable of his whole life. His financial position had greatly improved and his mind was crowded with new schemes and new ideas with reference to the study of the ocean. He visited the *Challenger* expedition when the ship reached Halifax in May, 1873. He was enthusiastic about our captures, and he could teach us much we did not know, especially about echinoderm and annelid larvæ. I remember he showed us how he had proved that *Tornaria* was the larva of *Balanoglossus*. All the younger men of the expedition were pronounced evolutionists or Darwinists, and the name of Agassiz conjured up opposition to such views, but the impression made by Alexander Agassiz was excellent in every direction, the general judgment being that the younger Agassiz was a very different man from his distinguished father. It was freely prophesied that he would have a very brilliant scientific future. He was buoyant, cheerful, confident and possessed a fund of dry humor. He was rather above medium height, with brown eyes and dark complexion. He had a fine presence, dignified bearing and gracious manners. The following note received on board the *Challenger* some months after his visits indicates conscious capacity and the overflowing joy of life: "We are all flourishing here after a very successful summer at Penikese, about which you must have seen plenty in the papers. The museum is getting fuller than an egg, and I don't know what we shall do for room. We have just secured the collection of Wachsmuth—the finest collection of *crinoids* there is from the west, and with what we have, our collection is now superb. I shall attack them soon I hope." (Cambridge, October 24, 1873.)

The scene, the outlook on life, was suddenly changed. His father, Louis Agassiz, died on December 14, 1873. His beloved wife, Anna Russell, who had tenderly nursed and watched at the bed-side of her father-in-law during his last illness, caught cold from exposure on the night of his death, and died from pneumonia within ten days thereafter.

This was a terrible blow to Alexander Agassiz. The light and brightness of his life had suddenly been extinguished. A cloud fell upon him which nothing on this earth could completely clear away. His mental attitude towards the future is plainly stated in a letter written from Peru in March, 1875, and received on board the *Challenger* when we were voyaging in the Pacific. It evoked the deep sympathy of the *Challenger* naturalists. He says:

> I hear of your whereabouts through the papers occasionally, though lately I have not seen anything concerning your movements, as I have been wandering about in Chili and Peru, out of the way of all newspapers. I could not stand the associations of my house after the terrible ordeal I had to pass through, and for about five months I have been listlessly running from place to place trying to wake up an interest in outside matters. It is all well enough as long as I am on the move, and there is the excitement of constantly seeing new things and new people, but when I am settled down for any length of time, and attempt to do any continuous work, it is impossible for me to throw off my troubles, and life seems unendurable. Yet I can not deny that I have had a great deal of pleasure on my trip to South America, and under ordinary circumstances it would have been to me a great store of future enjoyment. As it is I look upon it as so much time passed, and really dread the moment when I shall reach home, or rather my house, for no place can henceforth be a home to me.

Even here, however, what I have called the dominant note of his life—the desire to get new knowledge—rings out strongly, for the rest of this distressful letter is taken up with a detailed description of his

exploration of Lake Titicaca. He had taken his museum assistant with him to help in making collections for the museum at Cambridge, he had chartered the only available vessel, had taken water and air temperatures, had dredged and tow-netted and constructed a bathymetrical chart of this elevated lake, 12,500 feet above sea level—altogether a most interesting description from all points of view.

The Alexander Agassiz before the death of his wife in 1873 was, in my opinion, a very different man from the Alexander Agassiz after that sad event. The first Alexander Agassiz I had seen, but I knew him only very slightly. I have pictured him as he appears to me from his correspondence, from what I have heard from his intimates, and from his own lips. The second Alexander Agassiz I knew well, long and intimately, he was during the last thirty-four years one of my most intimate and valued scientific friends.

During his visit to the *Challenger* at Halifax he promised to come to England on the return of the expedition to see our deep-sea treasures. When he arrived in Edinburgh I referred to the death of his wife, but he held up his hands and said, "I can not bear it." His expression was such that the subject was never again mentioned, although he frequently spoke about his boys. He spent fully two months in Edinburgh, but would not at that time attend any social functions. Every day from early morning till as long as day-light lasted he assisted me in opening boxes and bottles and in separating out the various groups of marine organisms, especially selecting the echini, which he was to take to America, having consented to describe this group of organisms for the report on the scientific results of the expedition. While this work was going on we had abundant opportunity for discussing the work and results of the expedition and every aspect of the new science of the sea. I was relatively young, and often recounted to him the comic and other incidents of the voyage, and he would smile and seem amused. His attitude was, however, in striking contrast to the boisterous merriment of Haeckel when engaged with me in the same place and in similar occupations. On the conclusion of his visit he wrote to Wyville Thomson on January 23, 1877:

> I can't tell you what a pleasant time I have had in Edinburgh, thanks to you and Lady Thomson. It is really the first time since the death of father and my wife that I have felt in the least as if there were anything to live for, and I hope you have put me on the track to get into harness again and do my share of the work I have to do, if not with pleasure, at least cheerfully.

During the last thirty-five years of his life Alexander Agassiz's activities and interests were many and varied. The control and direction of the Calumet and Hecla mines demanded frequent visits to the west, and there we find him conducting valuable experiments in the distribution of underground temperatures in the great depths of the mine. We also find him producing carbonic acid gas to put out a disastrous fire in the mines—said to be the first time this method was thus employed on a large scale.

The first American attempt to found a zoological station at Penikese having failed, he established a zoological laboratory at Newport to take its place, equipping it with all the necessary appliances and accommodations for twelve students. This institution was carried on for twenty-five years—till it was no longer necessary owing to the establishment of the Woods Hole Marine Biological Station.

The important series of oceanographical or deep-sea investigations with which his name is so closely associated have won for

him the gratitude of all subsequent generations of scientific workers He directed three expeditions in the Atlantic in the U S. S *Blake*, and three in the Pacific in the U S. S *Albatross* These dealt especially with the deep-sea, and yielded an immense number of new organisms and new observations concerning the physical, chemical biological and geological conditions of the great ocean basins Agassiz, being a practical engineer, was able to suggest many improvements in deep-sea instruments and methods, the wire rope for dredging and a modified trawl for deep-sea work were among these improvements The general account of the Atlantic expeditions is published in two volumes entitled "Three Cruises of the *Blake*," and the general accounts of the Pacific expeditions are to be found in the bulletins and memoirs of the Museum of Comparative Zoology It would be difficult to overestimate the value of the zoological and other collections amassed during these most excellent and extensive explorations

If we can say that we now know the physical and biological conditions of the great ocean basins in their broad general outlines—and I believe we can do so—the present state of our knowledge is due to the combined work and observations of a great many men belonging to many nationalities, but most probably more to the work and inspiration of Alexander Agassiz than to any other single man Agassiz's researches in the Atlantic resulted in very definite knowledge concerning the submarine topography of the West Indian region and of the animals inhabiting these seas at all depths—probably we know more of this submarine area than of any other area of equal extent in the world because of his explorations. He arrived at the general result that the deep-sea animals of the Gulf of Panama were more closely allied to those in the deep waters of the Caribbean Sea than the Caribbean forms were to those of the deep Atlantic. Hence he concluded that the Caribbean Sea was at one time a bay of the Pacific Ocean, and that since Cretaceous times it had been cut off from the Pacific by the uprise of the Isthmus of Panama

When the *Challenger* expedition carried her explorations down through the central southern Pacific, she found a rather puzzling state of things. In deep water relatively very few animals were captured on the bottom of the ocean when compared with those taken in the great southern ocean or nearer continental shores, those obtained were, however, of rather pronounced archaic types The deposits in the same area were of surpassing interest, large quantities of a deep-brown clay were hauled up, in which were imbedded enormous numbers of manganese nodules and concretions, some of them being formed around sharks' teeth, ear bones and other bones of whales, and others around volcanic fragments mostly converted into palagonite Sometimes hundreds of sharks' teeth and dozens of whales' ear bones were captured in a single haul, and most of them belonged to extinct species. Small zeolitic crystals and crystal balls were also mixed up in these red-brown clays, evidently formed *in situ* More extraordinary still were the minute spherules having a hard black coating and an interior of pure iron and nickel, as well as other minute spherules, called chondres, found hitherto only in meteorites These spherules are believed to have an extra-terrestrial origin, and to have formed at one time the tails of meteorites or falling stars. This was a strange assemblage of things, and some scientific men argued that such a condition of matters must be regarded as local and accidental.

Now Alexander Agassiz explored anew this region of the earth's surface the furthest removed from the shores of continental land, and he found that the same condition of things extended over vast areas of the Pacific Ocean. Here we have almost certainly the region of minimum accumulation on the sea-floor, and recent investigations indicate that there is in these deep deposits more radio-active matter than anywhere else in the solid crust of our planet. A satisfactory and clear understanding of the phenomena has not yet been obtained, but Agassiz's researches take us a long way on the road to a solution of some exceedingly interesting and important oceanic problems.

During the last thirty years of his life, Agassiz became very greatly interested in all coral-reef problems, and organized very many extended expeditions, almost entirely at his own expense, with the view of studying coral reefs, coral islands, and upraised coral formations. It would be wearisome to give even an abstract of all the publications by himself and his assistants dealing more or less directly with these subjects. It can truly be said that he visited, explored and described with much detail every important coral-reef region of the world, in the Atlantic, Pacific and Indian oceans.

Agassiz's special interest in the coral-island problem was apparently first awakened during his visit to Edinburgh in 1876. I had sketched out a series of papers to be presented to the Royal Society of Edinburgh during that session, and he heard the first of these read, viz., "The Distribution of Volcanic Débris over the Floor of the Ocean, its Character, Source and some of the Products of its Disintegration and Decomposition." He became rather enthusiastic about the results arrived at in the paper. Another of these papers dealt with the distribution of carbonate of lime over the floor of the ocean and with coral-reef formations. One of the most striking results of the *Challenger* expedition was the discovery of enormous numbers of pelagic calcareous algæ, pelagic foraminifera and pelagic mollusca in the surface and sub-surface waters everywhere within tropical and subtropical regions, but the dead calcareous shells of these pelagic organisms were not distributed with similar uniformity over the floor of the ocean. In some places they formed pteropod and globigerina oozes, but in the very greatest depths not a trace of these shells could be found in the red clays which covered the bed of the ocean. It was observed that the thinner and more delicate shells disappeared first from the marine deposits with increasing depth, and only the thicker and more compact shells or their fragments reached the greater depths. These conclusions were verified again and again during the cruise of the *Challenger*, and subsequently by Agassiz in his expeditions. Evidently the calcareous shells were removed by the solvent action of sea-water as they fell towards, or shortly after they reached, the bottom of the ocean. In the shallower depths the majority of the shells reached the bottom before being completely dissolved, and there accumulated. The solvent action was also retarded in these lesser depths through the sea-water in direct contact with the deposit becoming saturated, and therefore unable to take up more lime. The explanations thus given to account for the disappearance of carbonate of lime from deep-sea deposits were then applied to the interpretation of the phenomena of coral atolls and barrier-reefs. It was argued that all the characteristic features of atolls and barrier-reefs could be explained by a reference to the biological, mechanical

and chemical processes everywhere going on in the ocean without calling in the extensive subsidences demanded by the theories of Darwin and Dana.

Agassiz almost at once adopted these views, saying, "I never really accepted the theories of Darwin and Dana; it was all too mighty simple. Besides," he added, "this new view is founded on observation and can be verified, and I'll attempt to do it, and will visit coral-reef regions for the purpose."

Darwin, it will be remembered, stated that his whole theory was thought out on the west coast of South America before he had seen a true coral reef.[4] The method of Agassiz was to see every true coral-reef region of the world before he formed any theory.

Darwin's theory of coral reefs may be briefly stated as follows: The corals commence by forming fringing reefs along a shore. The shore commences to subside, but the corals grow directly upwards. In course of time a lagoon-channel is formed between the growing reef and the subsiding shore-line. When this process continues for a sufficient length of time the central island completely disappears beneath the waves, and the lagoon of an atoll occupies ultimately the place of the island. The fringing reef thus develops into the barrier reef, and the barrier reef develops into the atoll.

Agassiz writes in 1909 that the result of his studies on coral reefs has been "to dissent *in toto* from the views of Dana and Darwin regarding the mode of formation of barrier reefs and atolls."

In 1902, after his visit to the Maldives, he wrote to me as follows:

> This will be the end of a most successful expedition, perhaps to me the most interesting visit to a coral reef group I have made. For certainly I have learned more at the Maldives about atolls than in all my past experience in the Pacific and elsewhere. I should never have forgiven myself had I not seen the Maldives with my own eyes and formed my own opinion of what they mean.—Such a lot of twaddle—it's all wrong what Darwin has said, and the charts ought to have shown him that he was talking nonsense. . . . At any rate I am glad that I always stuck to writing what I saw in each group and explained what I saw as best I could, without trying all the time to have an all embracing theory. Now, however, I am ready to have my say on coral reefs and to write a connected account of coral reefs based upon what I have seen. It will be a pleasure to me to write such a book and illustrate it properly by charts and photographs. But it will be quite a job with my other work on hand. I hope to live to 100! or rather I don't hope, but ought to! to finish all.

Later, in 1907, he writes: "I have started on my coral-reef book, but it is a job, a good deal more than I expected. If I stay at home I ought to make good progress." Later in the same year he says: "I fancy I shall have all the time I want to write out my popular account of coral reefs. I have made a fair beginning, and hope to keep the material within reasonable bounds and not allow it to run away with me." Four months before his death he wrote: "I have worked hard at my coral-reef book," and only a few days before his death he told me in London that he had really sketched out this book three times, but found it very difficult indeed to deal satisfactorily with the mass of information that had been collected. It was his intention, he stated, to write this book during the present year practically for the fourth and last time, leaving out all criticism of the work of others and stating exactly what he had himself observed and his own views.

When in 1903 he addressed the Royal Society of London on coral reefs, he simply described what he had seen in the various

[4] See "Life and Letters of Charles Darwin," Vol. I., p. 70, London, 1887.

coral-reef regions, and did not enter into any controversial matters. The real point of his address came out in the subsequent discussion, viz., that in all his investigations and voyages he had not seen one single atoll or barrier-reef which could be said to be an illustration of the Darwinian theory of coral reefs. It was evident to a large number of naturalists who had themselves observed in the field that the subsidence theory was no more necessary to account for the characteristic features of atolls and barrier reefs than the elevation theory of Darwin—published about the same time—was necessary to account for the Parallel Roads of Glen Roy in Scotland.[5]

It is difficult to account for the heated controversies which have raged around the coral-reef question. Possibly these would never have taken place had the subsidence theory not been associated with the name of Darwin. Very many of the public did not seem to realize that this theory of coral reefs was the work of Darwin when young and inexperienced, and had nothing whatever to do with the theory of natural selection. When the late Duke of Argyll published his famous article entitled "A Conspiracy of Silence," in the nineteenth century (September, 1887), he gave *Bathybius* and *coral-reef theories* as illustrations, and many people regarded the article as a suggestion that Darwinists and evolutionists were disposed to burke free discussion. This was hotly resented by Huxley and others, while some naturalists seem to have believed they were called upon to defend Darwin's coral-reef theory, although they had never seen or examined a coral-reef. Agassiz kept severely aloof from all these controversies, although he writes that he was much amused by the style of various articles and controversies. In one letter to me (March, 1888) he writes: "I am glad to see by last *Nature* that you are taking a hand in the coral discussion now that it has reached *hard bottom* and no longer deals with imaginary quantities, impossible algebra and metaphysical squibs."

All scientific men must regret that Agassiz was not spared to publish the long-expected summary of his coral-reef work, and to learn that he has not left behind any manuscript suitable for publication giving a connected statement of his views. Such a work from his pen would doubtless have been a splendid edifice erected on the magnificent foundation of observation laid with so much expense, trouble and care in the elaborate memoirs on the coral-reef regions he had visited in all parts of the world.

Throughout all these coral-reef investigations I have been in substantial agreement with Agassiz's views. In these circumstances I need make no apology for giving a short statement of the conclusions at which, I think, Agassiz had arrived as a result of his coral-reef investigations.

Agassiz claimed, I believe, to have shown that existing atolls and barrier reefs in no way indicate, even approximately, the former position of the shore lines around islands or along coasts now deeply submerged beneath the ocean.

The submerged banks from which atolls and barrier reefs now arise have been formed—that is, they have been built up or leveled down—in a great variety of ways, and at very different times. Each coral-reef region must in this regard be studied by itself, account being taken of

[5] See "Observations on the Parallel Roads of Glen Roy, and of other parts of Lochaber in Scotland, with an attempt to prove that they are of marine origin," *Phil. Trans.*, 1839, p. 39; *Edin. New Phil. Journ.*, Vol. XXVII., p. 395, 1839.

the surrounding physical and geological conditions.

The reefs themselves have been very largely—in some instances, predominantly—made up of lime-secreting organisms other than the so-called reef-building corals, such as calcareous algæ, foraminifera and corals other than true reef builders, many of which have a wide depth range.

The characteristic features of coral-reefs—the central shallow lagoon and the surrounding rim of living coral with deep water outside—are mainly to be explained by biological, chemical and mechanical activities continuously in operation at the present time, there being vigorous growth of all lime-secreting organisms wherever the conditions of life are most favorable, and less vigorous growth and even death of these organisms where the conditions are unfavorable. A detailed study of the favorable and unfavorable conditions for different species in an existing atoll seemed to Agassiz a great desideratum at the present time and I am delighted to learn that this is now being undertaken by American naturalists under the auspices of the Carnegie Institute.

In small atolls, where the surrounding reef is very extensive relatively to the enclosed lagoon, the lagoon tends to become filled up by the accumulation of coral sand, the deposition of carbonate of lime by the living organisms of the atoll being in excess of that removed in solution and by mechanical means, where the atoll is large, and the encircling reef is—relatively to the size of the lagoon—small, then the lime removed from the lagoon by solution and currents is greater than that deposited by living organisms; hence the lagoon becomes deeper and wider. The lagoon of Diego Garcia appeared to have increased considerably in area in this way between 1837 and 1885.

It is undoubtedly true that many coral-reef regions have been recently elevated. The circular atoll and barrier reef can not be accepted as evidence of subsidence, the characteristic features of coral reefs would be very similar in a stationary, in a slowly sinking or slowly rising area, although each would show secondary modifications. It matters not whether the change of sea-level be due to crustal movement, to attraction of elevated continental land, or to the accumulation or the melting of polar ice-masses.

When coral plantations rise from a submerged bank, the corals and other lime-secreting organisms situated towards the seaward edge would from the first have the advantage, they would hence reach the surface, before the central portions, where the corals would be in a position more or less unfavorable for vigorous growth. A shallow lagoon would thus be formed, which might subsequently be cleared by solution, and mechanical action of many of its living coral plantations.

The coral atoll, on reaching the surface would, he admitted, in very many cases advance seawards on a talus of its own débris, expanding like a fairy ring, and it seemed to him more than probable that the boring at Funafuti atoll was driven down into such a talus, with an underlying Tertiary base.

The red earth which is found on coral islands and supplies the food for plant life, is chiefly derived from the disintegration and decomposition of floating pumice, which is frequently thrown up by the waves on the reefs.

These results of Agassiz depend on a far greater number of original observations, in widely scattered areas, than have been made by all the other authorities on coral reefs put together.

When we attempt to survey the life-work of Alexander Agassiz, we are aston-

ished at its amount, variety and quality His activities in any one direction would have been an excellent record for any one man, but he was many sided He was largely engaged in commercial undertakings and directed a great business during the whole latter half of his life, he carried on detailed researches and published splendid memoirs on the group of echinoderms—a subject on which he was regarded as the leading authority In his deep-sea researches he added greatly to the world's knowledge of the great oceans, and inspired the investigations of a very large number of zoological and other specialists In his study of coral-reefs he traveled more extensively than any man of his time—many thousands of miles—with one special object in view—to see with his own eyes the varied forms which these gigantic and beautiful natural structures assume under different conditions We must likewise take into account his work in the laboratory and in the study, where the reports on his many voyages, cruises, travels and collections had to be prepared for publication Again one must recall the services he has rendered to his *alma mater*—Harvard University—in his general assistance in administration, his special care of its museums, his donations for extensions in many directions, and lastly his altogether grand series of publications from the Museum of Comparative Zoology [*] His great desire was to add to the sum of natural knowledge by his own work and by the impulse he could give to others imbued with a similar spirit and desire. He worked and struggled continuously and heroically with that end in view, and with those who are now engaged in working up his results and collections in all civilized countries he is still a living force, and will be so for many years to come, for he has arranged for the publication of all the results of these researches I used to meet him nearly every year either in Europe or in America, when we spent a few days together discussing almost all oceanic problems I am conscious of his effect on my life and all my scientific work As an example of the influence he exerted we have only to look at the introduction to the three splendid volumes recently published on the medusæ of the world by Alfred Goldsborough Mayer, where the initiation and encouragement of a generous master and friend are gracefully acknowledged Many instances might be cited to show how well and judiciously he applied his wealth to set agoing work which he considered worth doing, not only in his own time but also in the future The large number of decorations and honors which were conferred on Alexander Agassiz by governments and universities and by learned societies in all parts of the world show abundantly how highly his scientific labors were appreciated by his contemporaries

It has been truly said that man does not live by bread alone History is crowded with instances illustrating the fact that men have cast off this mortal coil as so much worthless dross when impelled by the demands of some spiritual truth Other men have endured the greatest hardships and privations in their endeavors to create the beautiful in form, in sound or in color. As it has been with the religious and artistic spirit in the past, so is it with the modern scientific spirit The desire to find out the secrets of nature impels men to trudge over Arctic and Antarctic ice-fields with the satisfaction of all bodily requirements reduced to a minimum and burdened with a load of scientific instruments. Other men expose their bodies to the at-

[*] Fifty-two volumes of the *Bulletin* and thirty-two volumes of *Memoirs*.

tacks of pestilential microbes for the advance of knowledge and the betterment of man's estate, while Alexander Agassiz rises with difficulty, when overwhelmed with sickness, and has his mattress laid on the deck of the tossing steamer in order that he may the better record the message which the dredge or trawl has brought to light from the dark abysses of the Atlantic or Pacific Ocean In such men the body has truly become merely the vehicle of the soul.

It has been said that Alexander Agassiz was a sad and reserved man It must be admitted that during the latter part of his life he was not so moved by joyous impulses as in his earlier years Those who knew him well did not find him reserved, and they can testify to the great pleasure he derived from a new discovery or a new view of the interrelations among natural phenomena

It has also been said that he did not interest himself in the deeper philosophical aspects of the researches in which he was engaged This I believe to be a mistake. He professed never to engage in discussions except where it was possible to verify one's conclusions by an appeal to observation or experiment Although he did not publish papers dealing directly with philosophical subjects, still he was keenly interested in all evolutionary problems He used to say that Darwin had probably explained the survival but not the arrival of species, and he looked forward to a great increase of knowledge from experiments in Mendelism He believed that the mutation theory had received remarkable confirmation by experiments carried on in recent years He believed that the doctrines of heredity, which had been so successfully applied to the improvement of domestic plants and animals, would, in the not very distant future, be in like manner applied for the elevation of the human species, the most important of all domestic organisms. He felt convinced that the modern theories as to electrons, the disruption of atoms, and as to energy configurations in the ether being the sole ultimate phenomenal basis of matter would in time profoundly affect the philosophical outlook of many naturalists and their mental attitude generally towards materialism and the riddles of the universe The study of the world of physical and mental phenomena, he would say, was sufficient for this life The deeper and more earnestly these were investigated, the brighter and more definite would become the glimpses of that eternal something lying behind all manifestations, which in the meantime he was content to reverence His religious feelings seemed to be best expressed as a yearning after a higher and better life, which he held would become more attainable and more pronounced as mankind advanced in scientific knowledge Like all great men he was

> A dreamer of the common dreams,
> A fisher in familiar streams
> He chased the transitory gleams
> That all pursue,
> But on his lips the eternal themes
> Again were new

Great he unquestionably was. Great in his power for work, great in his conception of duty, great in his desire to add to natural knowledge, great in the height of his love, great in the depth of his sorrow, great in his elevated personality, great in his admiration for his university, great in his patriotism, great in his ideas as to the destiny of our race, great in his influence for good, like the genial and vivifying rain from heaven. Like all of us he doubtless had faults, both hereditary and acquired We know that

His life was gentle, and the elements
So mix'd in him, that Nature might stand up
And say to all the world, "This was a man!"

When his near relatives and dear friends affectionately laid his mortal remains beside those of his beloved wife last March in the Forest Hills Cemetery, well might they ask—

What hallows ground where heroes sleep?
'Tis not the sculptured piles you heap
But strew his ashes to the wind,
Whose sword or pen has served mankind
And is he dead, whose glorious mind
Lifts mine on high?
To live in hearts we leave behind
Is not to die

JOHN MURRAY

CHARLES M SCAMMON

CAPTAIN CHARLES M SCAMMON, U S R M, retired, senior officer of the service, died at his home, in East Oakland, Cal, May 2, in his eighty-sixth year His death followed in less than twenty-four hours after that of his wife to whom he had been united for sixty-five years

Captain Scammon was a native of Maine and came to the west coast in 1853, and for a time was engaged in the pursuit of whaling He was the discoverer of the large lagoon on the west coast of Lower California in latitude 27° 50′, which has since borne his name In 1861 he joined the revenue service with which he was connected until his death He was detailed by the government to assist in the explorations of the Overland Telegraph Expedition in 1865, and commanded the flagship of their fleet for three years To his intelligent and kindly cooperation the scientific corps of that expedition owed much of their success. Captain Scammon early became interested in the natural history of the marine mammals of the Pacific coast, and in those days before the invention of photographic dry plates, spared no trouble in gathering measurements, drawings and other data bearing on the cetacea. In 1874 these investigations were summed up in his finely illustrated quarto volume on the "Marine Mammals of the Northwestern Coast of North America," which forms the most important contribution to the life history of these animals ever published and will remain a worthy monument to his memory

WM H DALL

SCIENTIFIC NOTES AND NEWS

PROFESSOR E C PICKERING, director of the Harvard College Observatory, has been created knight of the Prussian order Pour le mérite Simon Newcomb and Alexander Agassiz are the only other American men of science on whom this honor has been conferred

DR THEODORE WILLIAM RICHARDS, professor of chemistry at Harvard, who is going to England at the invitation of the Chemical Society to deliver the Faraday lecture, will be given the honorary degree of D Sc by the University of Manchester on July 8

DR FREDERICK W TRUE, who has held the position of head curator of the department of biology in the U S National Museum since 1897, has been appointed assistant secretary of the Smithsonian Institution in charge of the library and exchanges

LORD CURZON, of Kedleston, has been elected president of the Royal Geographical Society in succession to Major Leonard Darwin

THE Hanbury medal of the London Pharmaceutical Society for 1911 has been awarded to M Jean Eugène Léger, chief pharmacist to the Hôpital St Louis, Paris

THE Royal Academy of Sciences of Berlin has elected Dr James George Frazer, fellow of Trinity College, Cambridge, and professor of social anthropology at Liverpool University, a member of the Philosophical-Historical Section

THE American Philosophical Society at its recent meeting, elected the following residents of the United States to membership George A Barton, professor of Semitic languages, Bryn Mawr College, Bertram Borden Boltwood, professor of radio-chemistry, Yale Uni-

versity; Lewis Boss, director of the Dudley Observatory, Albany, N Y, John Mason Clarke, state geologist and paleontologist and director of the State Museum and Science Division of the Educational Department, Albany, N Y, W M L Coplin, professor of pathology and bacteriology, Jefferson Medical College, Philadelphia, John Dewey, professor of philosophy, Columbia University; L O. Howard, chief of the Division of Entomology, U S Department of Agriculture, Joseph P Iddings, Washington, D C, Alba B. Johnson, Baldwin Locomotive Works, Philadelphia, Pa; A A Noyes, professor of physical chemistry, Massachusetts Institute of Technology, G H Parker, professor of zoology, Harvard University, A Lawrence Rotch, director of the Blue Hill Meteorological Observatory and professor of meteorology, Harvard University, Dr Leo S Rowe, Philadelphia, Pa, Dr William T Sedgwick, professor of biology at the Massachusetts Institute of Technology and biologist of the Massachusetts State Board of Health, and Dr Augustus Trowbridge, professor of physics at Princeton University The following foreign residents were elected Dr Svante Arrhenius, director of the Nobel Institute, Stockholm; J B E Bornet, Paris, Sir John Murray, Edinburgh

Professor Ugo Mondella, director of the geophysical observatory at Leghorn, has been appointed director of the Observatorio Regional do Rio Grande do Sul, Porto Alegre, Brazil

The delegates of the University Museum, Oxford, have appointed Dr. H. L. Bowman, fellow of Magdalen College and Waynflete professor of mineralogy, to be their secretary, in place of Mr H Balfour, curator of the Pitt-Rivers Museum, who resigns that office next month.

Mr. J. Clyde Marquis, instructor in agricultural journalism and agricultural editor at the University of Wisconsin, has accepted the position of agricultural editor of the *Country Gentleman*, recently purchased by the Curtis Publishing Company, Philadelphia. Mr. John Y. Beaty, associate editor of *Farm and Home* and the *Orange Judd Farmer*, has been appointed instructor in agricultural journalism and agricultural editor in place of Mr Marquis

The Academy of Natural Sciences of Philadelphia has appointed the following delegates Professor Carlo Emery to the fifty-year jubilee of Professor Giovanni Capellini, Professor G O Sars to the centennial anniversary of the founding of the University of Christiania and Mr Henry G Bryant to the tenth International Geographical Congress

Professor W B Herms, of the University of California, is on his way to Europe where, during the summer, he will visit the principal parasitological laboratories of England, France, Germany and Italy He will represent the University of California as authorized delegate to the International Hygiene Exhibit at Dresden

Mr William Bateson, F R S, has been appointed Herbert Spencer Lecturer at Oxford for 1911

Dr. William T. Sedgwick, professor of biology in the Massachusetts Institute of Technology, will give the commencement address at the Worcester Polytechnic Institute on "Science and the State"

Professor W. J. V. Osterhout addressed the Biological Society of Smith College, May 18, on "Some Aspects of the Action of Mineral Salts on Plants"

Dr G B. D de Nancrede, of the medical department of the University of Michigan, will give the commencement address before the Medical College of the University of Nebraska, at Omaha, May 18 His subject will be "False and True Professional Success."

Professor H. H Turner delivered the Halley Lecture at Oxford on May 22, his subject being "The Movements of the Stars."

Professor B. G. Wilder was born in Boston, not (as stated in our last issue) in Brookline, where his boyhood was passed.

WE learn from *Nature* that the committee of the Robert Koch memorial endowment for the encouragement of research in the subject of tuberculosis has decided to give grants to Professor Schieck and Dr Krusius for investigations on tuberculosis of the eyes, to Dr. Weinberg for statistical inquiries relative to tuberculosis and to Professor Gaffky for the continuation of his researches Since the year 1908 the sum of £3,000 has been expended by the committee in scientific work

A STATUE to the memory of Priestley is to be erected in the market-place of Birstall, the town of his birth

It is proposed to erect a monument to Richard Lander at Forcados on the lower Niger, of which he was the discoverer

DR STANFORD EMERSON CHAILLÉ, for forty-one years professor of physiology and pathological anatomy in the medical department of Tulane University, retiring as professor emeritus in 1908, eminent for his contributions to hygiene and public health, died on May 28 in his eighty-first year

PROFESSOR SOLOMON WOOLF, professor emeritus of drawing and descriptive geometry in the College of the City of New York, died on May 27 He was born in Mobile, Ala, seventy years ago, and was graduated from the College of the City of New York in 1859 He remained there as instructor and professor for the rest of his life, being made professor emeritus in 1901.

PROFESSOR KEINOSUKE OTAKI, professor of ichthyology and fishery matters in the Agricultural College at Sapporo, Japan, died on April 26, 1911, his death being the result of an injury in a railway accident three years before, from which he never recovered He was the first Japanese student to enter Stanford University, from which he graduated in 1894. He devoted himself to research on the fisheries, was for a time an assistant on the United States Fish Commission, and is the author of several valuable papers on the fishes and fisheries of Japan. For some ten years he was professor of English in the Imperial Military Academy in Tokyo He was one of the most active and efficient of the Japanese naturalists.

DR N STORY MASKELYNE, from 1856 to 1895 professor of mineralogy at Oxford, died on May 27, in his eighty-eighth year.

THE fifth International Philosophical Congress will hold its meeting in the buildings of the University of London in the spring of 1915

THE Otho S A Sprague Memorial Institute was organized in January, 1911 It is a memorial to the late Otho S A Sprague, who for many years was a resident of Chicago and who died about two years ago in Pasadena, California Mr Sprague designated his brother, A A Sprague, as the chief instrument through whom funds left by will should be expended The institute was organized by Mr A A Sprague with the following named gentlemen as members of the corporation and the first board of directors Martin A Ryerson, Charles L Hutchison, A C Bartlett, Byron L Smith, Albert A Sprague, 2d, Dr Frank Billings, John P Wilson and Albert A Sprague For the present the directors have decided upon medical research as the chief object for which the income of the memorial funds shall be expended and have selected Dr H Gideon Wells, associate professor of pathology in the University of Chicago and Rush Medical College, to direct research in medical problems The work will be done in cooperation with existing institutions, viz, the University of Chicago, Rush Medical College, the Presbyterian Hospital and the Children's Memorial Hospital of Chicago The institute will command a definite number of beds in the Presbyterian Hospital for the study of any diseases under investigation An advisory council has been appointed consisting of Drs. Frank Billings, James B Herrick, Joseph L. Miller and Professors E. R. Le Count, Ludvig Hektoen, E O. Jordan and Julius Stieglitz.

THE Surgeon-General of the army announces that preliminary examinations for

the appointment of first lieutenants in the Army Medical Corps will be held on July 10, 1911, and September 5, 1911 Full information concerning these examinations can be procured upon application to the "Surgeon-General, U S Army, Washington, D C" The essential requirements to securing an invitation are that the applicant shall be a citizen of the United States, shall be between 22 and 30 years of age, a graduate of a medical school legally authorized to confer the degree of doctor of medicine, shall be of good moral character and habits, and shall have had at least one year's hospital training, after graduation The examinations will be held concurrently throughout the country at points where boards can be convened Due consideration will be given to localities from which applications are received, in order to lessen the traveling expenses of applicants as much as possible The examination in subjects of general education (mathematics, geography, history, general literature and Latin) may be omitted in the case of applicants holding diplomas from reputable literary or scientific colleges, normal schools or high schools, or graduates of medical schools which require an entrance examination satisfactory to the faculty of the Army Medical School In order to perfect all necessary arrangements for the examination, applications must be complete and in possession of the Adjutant General at least three weeks before the date of examination Early attention is therefore enjoined upon all intending applicants There are at present sixty-one vacancies in the Medical Corps of the Army

A BIOLOGICAL party from the University of Nebraska has been formed for the purpose of carrying on ecological work in central and western Nebraska during the coming summer The party will spend all the time between June 15 and September 15 in the field, dividing the period between three selected stations, where sets of recording apparatus will be installed, and from these making excursions to other points The party includes Dr. Robt H. Wolcott and Mr. Frank H. Shoemaker, of the department of zoology, and Professor Raymond J Pool, of the department of botany, from the university, and Professor Cyrus V Williams, professor of botany in Nebraska Wesleyan University In addition to those named, who will devote the whole summer to the work, other persons specializing in certain lines will be with the party for shorter periods at different times during the summer The particular problems which the party will deal with are concerned with the ecology of the sandhill region of Nebraska and the biological conditions in the Cherry County lakes

SPEAKING in the House of Commons on the budget proposals, Mr Balfour, as quoted in *Nature*, asked the chancellor of the exchequer to exercise caution in carrying out his scheme for the expenditure of large sums of money on building consumption sanatoria In the public mind, he said, there had perhaps been an exaggerated enthusiasm for this method of dealing with tuberculosis There was an idea that this open-air treatment had produced such marvelous results that through it alone tuberculosis could be, if not exterminated, at all events diminished to such an extent that it might be reduced to one of the rare zymotic diseases. He was not sure that the most recent investigations bore out that view There were very able investigators who took the view, after examining the actual results in England and in Germany, that so many complete cures must not be expected as was at one time hoped for He took a sanguine view as to the treatment of tuberculosis, for he believed that science had made great strides and was still destined to make great strides, but when they came to such large sums as those mentioned by the chancellor of the exchequer, it was possible to waste money on permanent buildings which might be better devoted to scientific investigation into the cause of the disease They must not assume that all that they had to do was to spend money on these sanatoria in order to effect a cure. What was important was that medical science had made great progress, and we re-

quired further investigation and perpetual study as to how these people were to be treated when in the sanatoria One of the greatest benefits, perhaps, of establishing these sanatoria would be in giving expert medical authorities the opportunity of carrying on investigations which would enable them in the future to deal with this disease in a way they were not able to do at present In reply, Mr Lloyd George said he agreed that the important thing was to encourage scientific investigation, so as to arrive at the best methods of cure That was provided for in his bill There would be set aside a special fund for the purposes of scientific research The government would make use of and assist existing sanatoria, those which had been maintained by voluntary contributions, and even those which were built by private enterprise

UNIVERSITY AND EDUCATIONAL NEWS

MR MORTON P PLANT has offered to give an endowment of $1,000,000 for the woman's college which is to be established at New London, Conn It is a condition that the name shall be changed to the Connecticut College for Women

THE General Educational Board has made public a list of its latest appropriations for colleges and schools, amounting in all to $634,000 All the gifts to colleges are conditional and are applied to endowment only Other gifts may be applied to current expenses The list follows

College	Appropriation	To Be Raised
Converse, Spartansburg, S C	$50,000	$100,000
Drury, Springfield, Mo	75,000	325,000
Franklin, Franklin, Ind	75,000	325,000
Franklin and Marshall, Lancaster, Pa	50,000	225,000
Huron, Huron, S D	100,000	100,000
Pennsylvania, Gettysburg, Pa	50,000	150,000
Totals	$400,000	$1,225,000

Appropriations aggregating $68,000 went to the education of southern negroes, $130,000 is set aside for demonstration work in agriculture, also in southern states, under the supervision of Bradford Knapp, and $36,000 for professors of secondary education in state universities of the south

BROWN UNIVERSITY receives a bequest of $85,000 from Oliver Henry Arnold, M D, of Providence

THE Boston Edison Company will give the Massachusetts Institute of Technology $3,000 for a period of years for the purpose of electrical research involving a thorough investigation of the use of electricity in vehicles employed in trucking or delivery

WESLEYAN UNIVERSITY has purchased ground from the Russell estate as a site for a new observatory, which will be erected from the proceeds of a fund given in 1903 by Mr Joseph Van Vleck This gift has been increased by others, and now approaches $60,000

SIR FELIX SEMON, M D, has transferred to the University of London, for the foundation of a lectureship in laryngology, a sum of money amounting to £1,040 presented to him by the British laryngologists on his retirement from practise

THE Connecticut Agricultural College will conduct from July 5 to 28 a summer school of nature study, agriculture and agricultural pedagogy, of which Professor A F Blakeslee is the director

PROFESSOR GEORGE F KAY, who has been for four years professor of petrology and economic geology in the University of Iowa, has been elected head of the department of geology to succeed Dr Samuel Calvin, who died on April 17 Professor Kay has also been chosen by the Geological Board to succeed Professor Calvin as director of the State Geological Survey

DR CHARLES LINCOLN EDWARDS has been appointed assistant professor of biology and assistant director of the marine biological station in the University of Southern California.

LIEUT COL WIRT ROBINSON, Coast Artillery, has been nominated by the president to be professor of chemistry at West Point, to take

effect on October 3, to succeed Col. Samuel E. Tillman, who has been the head of the department of chemistry, mineralogy and geology since December 21, 1880, and retires for age on October 2.

The following changes take place in the department of philosophy in the University of Michigan: Professor Alfred H. Lloyd has leave of absence for the year 1911-12. During his absence Charles Milton Perry, Ph.D. (Mich.), joins the staff as instructor in philosophy. Dr. John F. Shepard, instructor in psychology, has been advanced to an assistant professorship. An additional instructorship in psychology has been created. It will be filled by Henry Foster Adams, Ph.D. (Chicago). Harry Wolven Crane, A.B. (Mich.), at present assistant in psychology, has been elected to the George S. Morris memorial fellowship for the year 1911-12.

The following appointments have been made at McGill University: Dr. N. H. Alcock, to the chair of physiology; Associate Professor Ernest Brown, to be professor of applied mechanics and hydraulics; H. Barton, to be professor of animal husbandry at Macdonald College. The following promotions have been made in the faculty of applied science: Mr. Batho, assistant professor of mechanics; Mr. Graham, assistant professor of mineralogy; G. M. G. Johnston, assistant professor of chemistry; H. M. Lamb, assistant professor of civil engineering; S. W. Werner, lecturer in assaying.

DISCUSSION AND CORRESPONDENCE

ACADEMIC AND INDUSTRIAL EFFICIENCY

There is one way in which the efficiency of industrial concerns and of educational institutions can be compared effectively, viz., in the administration of the finances.

In the following paragraphs, a number of representative educational institutions are compared to the railways of the United States as to the ratio of compensation of labor to operating expenses.

According to "Railway Statistics of the U. S. of America for the year ending June 30, 1909,"[1] the ratio of compensation of labor to operating expenses is 62.06 per cent, which, if we except one year, is the highest ratio in eleven years past.

Moreover, we might state that the usual rule for industries in general is that about 65 per cent of operating expenses goes to labor.

In the case of the railway statistics quoted above the salaries of administrative officers, "clerks" and "all other employees" are included, as shown on page 36, and as expressly stated to the writer of this article by the compiler of the statistics.

Thus in the following statistics on educational institutions, salaries of administrative officers and all other employees, are included along with the "productive" laborers, in this case, the teachers.

And, moreover, we must remember here that while a railway administrative officer is *only* an administrator and in no wise "productive," the administrative officer of the university or college is often, and indeed, in colleges prevalently, also a teacher and thus is "productive."

Moreover, the highest salaried officers in educational institutions are in all cases "productive" whether they do actual class-room teaching or not. Presidents and deans in all colleges and universities are productive, in that they lecture a good deal, and hold numberless consultations with students which are as valuable, or more so, to the latter as are the consultations with the professors.

But the institution which pays the most to "productive" labor is the most efficient.

The following schools were selected simply because they are typical of certain kinds of schools and not because they show high efficiency in the matter under discussion. Indeed they are not higher than the average, as far as I know. Other institutions which were investigated, and which might be quoted, show practically the same ratio as those here quoted.

A number of schools showing a low ratio of

[1] Slason Thompson, Bureau of Railway News and Statistics, Chicago, 1910.

compensation of labor to operating expenses might be quoted, but that does not necessarily say anything against the educational efficiency of those schools. The teaching staff may indeed be highly efficient. It simply indicates that too much is being paid for non-essentials as over against teaching, which latter we must consider the main business of the college.

Again it must be borne in mind that in every college in the land there is included in the operating expense a considerable per cent of money which goes to fellowships, scholarships and other "charitable" purposes, as, for example, subsidizing boarding-clubs, college papers, etc. If this money were not thus devoted to "charity" it might be spent for additional productive labor.[8]

Thus the seven institutions quoted show a ratio of 66.5+ per cent compensation of labor to operating expense while the railroads show a ratio of only 62.06 per cent.

	Year Ending	Paid to Labor	Operating Expenses	Per Cent
Throop Polytechnic Institute	Sept. 14, 1909	$50,000.00	$66,100.16	75.6+
Princeton University	July 31, 1910	462,508.42	701,679.25	65.9+
Baker University	July 15, 1910	43,801.67	64,637.61	67.7+
University of Kansas	June 30, 1910	290,788.55	429,655.93	67.6+
University of Okla.	June 30, 1910	93,599.81	125,659.08	74.4+
Howard University (federal institution)	June 30, 1910	55,450.00	119,574.40	46.3+
Marietta College	May 31, 1910	27,405.45	40,375.67	68.1+
			Average	66.5+

Moreover, less of the labor paid out of college funds is non-productive than in the case of the railroads.

And, finally, operating expense in the case of colleges includes a considerable per cent of moneys which are devoted to "charity" by which the public profits.

C. H. HANDSCHIN

THE DIRECTOR VERSUS NEWTON

IN this case the following conversation reported by Professor Maclaurin in SCIENCE, XXXIII., 103, January, 1911, has just come to my notice.

Supt. Your theory of gravitation is hanging fire unduly. The director insists on a finished report, filed in his office by 9 A.M. Monday next, summarized on one page, type written, and the main points underlined. Also a careful estimate of the cost of the research per student hour.

Newton. But there is one difficulty that has been puzzling me for fourteen years, and I am not quite....

Supt. (with snap and vigor). Guess you had better overcome that difficulty by Monday morning or quit.

I have heard since that the conversation was continued as follows, and I wonder if the director was not right.

Newton. I shall continue to use my own judgment about the disposal of my time.

Supt. Yes, but no scientific man should go fourteen years, or even seven, without publishing results. Fourteen years ago you ranked among the leading thousand scientific men, but seven years ago your name was dropped, and this year it was not restored. A city that is set on a hill can not be hid.

Newton. Still I think I am right.

Supt. But the director thinks that, as long as you are accepting pay as a leading scientific man, you should *publish* enough results to keep up your reputation.

CHARLES ROBERTSON

CARLINVILLE, ILL.,

AN ENGLISH COURSE FOR ENGINEERING STUDENTS

TO THE EDITOR OF SCIENCE: I am not writing at present to discuss that much-discussed topic, the teaching of practical composition to engineering students, but to explain the first semester work in a course for freshman engineers given at the University of Minnesota, a two-hour course in English which goes hand in hand with a two-hour course in the more practical composition. Two authors are studied, Arnold and Huxley, the former in Gates's "Selections from Matthew Arnold," and the latter in Snell's "Autobiography and Selected Essays by Thomas Henry Huxley" in the Riverside Literature Series.

[8] In the University of Chicago 7.6 per cent. of operating expenses goes to fellowships and scholarships alone. A majority of the larger institutions will show a similar per cent.

To the boy who enters the engineering college fresh from high school, the reading of Arnold's "Sweetness and Light," "Hebraism and Hellenism," etc., is both stimulating and broadening. It forces the freshman to think, to sum up his own ideas concerning his relation to life and the world about him, and perhaps, before he realizes it, his outlook on life has widened. Arnold teaches him to value himself for what he is, to understand what ideal perfection is, to attempt, specialist though he be, to prepare himself for a well-balanced life. The results of Arnold's teaching I have found in impromptu paragraphs on "My Aim in Life," written in the composition class. Here, back of an occasional obvious effort to write what might please the instructor, I have seen evidence of a sincere desire on the student's part to be not only a perfect engineer, but a well-rounded man as well.

The transition to Huxley is made through his controversy with Arnold over the means of getting a cultural education. In Percival and Jelliffe's "Specimens of Exposition and Argument" which the men use in their composition course, is Huxley's address at the opening of Sir Josiah Mason's Scientific College in Birmingham. Arnold's reply is in Gates's "Selections." This controversy gives the freshman a good idea of different views of education, especially of scientific education, and paves the way for Huxley's talks on "A Liberal Education," "Principal Subjects of Education" and "On Improving Natural Knowledge."

The subject-matter and structure of Huxley's addresses appeal to the freshman engineer. This part of the course fits in particularly well with the exposition work in composition. The student learns how to fit his material to his audience, how to outline clearly, how to say things most concisely and in the strongest way, and the fact which the autobiography gives us, that Huxley at first detested writing and speaking, encourages the freshman to emulate Huxley's example and master his mother tongue, that he, too, may best put his ideas before others. As to the subject-matter, what is better fitted to interest the scientific student than "On a Piece of Chalk," "Coral and Coral Reefs" or "The Physical Basis of Life"? Such essays open up for him the great facts of nature which have come in with the "new knowledge."

The fact that this course, joined to the course in practical composition (which is another story), is required of all engineering freshmen and that it is the only course of its kind which they will ever get in college, makes the question of proper subject-matter of vital importance. I should welcome criticism and suggestions.

CHARLES WASHBURN NICHOLS
THE UNIVERSITY OF MINNESOTA,

A KINETIC THEORY OF GRAVITATION

TO THE EDITOR OF SCIENCE: In reading the article entitled "A Kinetic Theory of Gravitation," which was published by Dr. Brush in SCIENCE for March 10, I was at once struck with what seemed to me a fallacy in an illustration given early in the discussion. Perhaps the point at issue has been sufficiently discussed by Dr. Kent in SCIENCE for April 21, but since it presented itself to me somewhat differently it may not be out of place to give my line of reasoning.

I refer to the consideration by Dr. Brush of the case of the transportation of a one-pound mass from the surface of the earth to a point of equilibrium between the earth and the moon, at which point there would be no tendency for the body to move either toward the earth or toward the moon. As I understand the argument of Dr. Brush he assumes that in this case there is an apparent disappearance of energy, that there is no gain in the potential energy of the system caused by raising this body from the surface of the earth to the position of equilibrium and that there is, so to speak, nothing to show for the work done in so raising it.

The point that Dr. Brush seems to have overlooked is that attraction between two bodies is mutual. If the pound mass in the position of equilibrium is attracted by earth

and moon it in turn attracts both earth and moon The tendency for the earth and moon to approach each other is greater than before the pound mass was raised from the surface of the earth, the potential energy of the system is increased by an amount equal to the energy expended in raising it and there is no more a disappearance of energy to be accounted for than in the simpler case where a mass subject to no attraction but the earth's is raised above the earth

SCIENTIFIC BOOKS

Œdema A Study of the Physiology and Pathology of Water Absorption by the Living Organism By MARTIN FISCHER, M D Pp 209 New York, John Wiley and Sons 1910

A trenchant alternative to current and generally accepted ideas of the distribution of water in the organism is presented by Fischer in this essay The familiar reference to filtration, diffusion and osmosis as explanatory factors is notably absent and, instead, the part played by the colloids in the cells and body fluids is emphasized That some colloids, such as gelatine, for example, are able to take up water and thus enormously to increase their volume is common experience Such "hydrophilic" colloids Fischer has investigated with reference to the conditions which cause them to take in water or to give it forth The degree of swelling of the colloid depends on its nature and also on the character of the solution in which it is placed Thus both gelatine and fibrin swell more in alkaline or acid solutions than in water, both have the amount of swelling in acid or alkaline solutions reduced by the presence of electrolytes, and in both the addition of non-electrolytes fails to exert the checking effect produced by electrolytes By extensive experiments Fischer has demonstrated that the body tissues, represented by muscle and the eyes, when immersed in water, or in acid and alkaline solutions, or in combinations of acid and alkaline solutions with various electrolytes, behave in a manner quite analogous to gelatine and fibrin

On the basis of these experiments the suggestion is offered that œdema is induced whenever, in the presence of an adequate supply of water, the affinity of the colloids of the tissues for water is increased above what we call normal Particularly by the accumulation of acids in the tissues is the affinity for water increased Thereupon Fischer proceeds to show that states in which œdema develops are accompanied by an abnormal production of acid, that under such circumstances œdema can be reduced by the same agencies (electrolytes) which decrease the affinity of hydrophilic colloids for water, but remains unaffected by non-electrolytes, and that experimental production of acids in tissues results in the development of œdema

The argument thus devised for the explanation of œdema in general is applied to the peculiar phenomena of œdema in special organs, and is then extended to other biological phenomena in which the transfer of water plays an important rôle, as in hæmolysis, growth and urinary secretion

The experimental procedures on which the conception described in this volume is founded are of the utmost simplicity, and can be readily tested by any one Fischer's application of these simple tests to conditions in the body is made with much ingenuity and in many instances with compelling conviction To what extent the process can be used to explain certain results of experimental procedures which cause increased production of lymph, or which vary the amount of urine secretion, remains to be seen Certainly the conception is highly suggestive, and well worth putting to further test

The subject is expounded by Fischer with clearness, with enthusiasm, and with evident assurance of the adequacy of the theory to meet the demands that can be put upon it The essay was awarded the Nathan Lewis Hatfield Prize by the College of Physicians of Philadelphia in 1909.

W B CANNON

Introductory Notes on Quantitative Chemical Analysis. By CHARLES WILLIAM FOULK, Professor of Analytical Chemistry in the Ohio State University. Second edition, revised and enlarged. Columbus, Ohio. 1910.

This is a very detailed but simple manual for college work in quantitative analysis. 130 out of 239 pages are given to general principles and methods. Detailed description of 14 practical analyses occupies the remainder of the volume.

E. R.

Qualitative Chemical Analysis, Organic and Inorganic. By F. MOLLWO PERKIN, Ph.D., Late Head of the Chemistry Department, Borough Polytechnic Institute, London. Third edition. New York, Longmans, Green, & Co.

This is an excellent manual of systematic, qualitative, inorganic analysis followed by a manual of qualitative organic analysis, the latter necessarily consists chiefly of special tests. It will doubtless be found useful.

E. R.

Publications of the Astronomical and Astrophysical Society of America. Vol. 1, pp. xxvii + 347. Ann Arbor, Mich. 1910.

This volume, published by authorization of the society at its tenth annual meeting in 1909, is devoted (after a brief introductory sketch) to accounts of its meetings, including the two informal conferences which preceded its organization, and to abstracts of the papers presented. The last occupy by far the greater part of the work. To review them would be practically to give an account of the astronomical work done in this country in the last twelve years.

Perhaps the strongest impression left after glancing over them is of the advance that has been made, both in the means and results of observation, since the first conference was held at the dedication of the Yerkes Observatory in 1897.

To the members of the society nothing is likely to be more prominent in memory than the inspiration resulting from its meetings, with their abundant opportunity for conference and discussion, and the cordial hospitality shown at the various places of meeting.

SPECIAL ARTICLES

THE "DILUTE" FORMS OF YELLOW MICE[1]

A MODIFIED variety of the dark-eyed black mouse exists in the dilute black or "blue" of the fanciers. When the hairs of these dilute black animals are examined microscopically and compared with those of ordinary or intense blacks, it will be found that a reduction in the number of the pigment granules has taken place. It is not a large reduction, but is nevertheless sufficiently pronounced to be recognized with considerable ease. The same relation is observable between the intense and the dilute varieties of brown, known as "chocolate" and "silver-fawn," respectively, as well as in the corresponding varieties of black-agouti and brown-agouti.

The hairs of cream, or light yellow, mice, as compared with those of ordinary yellow mice, show, when examined microscopically, a very pronounced reduction in the amount of yellow pigment. This reduction is clearly more complete than that seen in the dilute black or dilute brown forms. Moreover, the last two forms named are remarkably constant in their degree of dilution, while cream forms may vary through deep creams to light yellows and from these to deep red-orange forms showing a full complement of pigment granules.

It is known that in the case of brown and black the dilute condition behaves as an independent unit-character, and so can be transferred in crosses from brown to black or *vice versa.* The dilute condition is also recessive to the intense, in crosses, so that dilute animals bred together produce only dilute offspring.

The question now arises whether "cream"

[1] Contributions from the Laboratory of Genetics, Bussey Institution, Harvard University, No. 11.

is a dilute form of yellow corresponding in nature to the dilute forms of black and brown A very simple and direct test of this matter is obtained by breeding "cream" animals together

Cream-colored, like all other shades of yellow mice, are regularly heterozygous, producing black or brown pigmented young as well as those which are yellow, the yellows being to the non-yellows approximately as two to one[5] Now if the "cream" condition of yellow is produced by the same factor as the dilute condition of black and brown, the "creams" bred together should produce non-yellow young all of which are *dilute*, since, as stated, dilution is recessive in nature

Such, however, is not the case Cream animals mated together produce only cream or light-colored yellow offspring, but the black or brown pigmented young which they produce are commonly of full intensity Accordingly, it follows that the "cream" modification of yellow is different in nature from the dilute modification of black and must be produced by a different factor

This fact being established, search was begun for a type of yellow which when bred by itself would produce yellows and dilute forms of black and brown Such yellows should, when obtained, be distinguishable from the intense yellow as well as the "cream" type, and should show on microscopic examination of the hair a condition of pigment reduction equal in amount to that seen in the dilute black or dilute brown forms

Such yellows have been obtained They may be deep red, light cream, or any of the intermediate gradations, but they possess an extremely characteristic washed-out dull appearance, which serves to distinguish them clearly from intense forms, even though these be extremely light colored.

Since this form of yellow occurs in all the gradations from "red" to "cream," it is apparent that it represents an independent form of pigment reduction; and since, unlike the "cream" reduction, it is transferable to black or brown, it is safe to class it as the *dilute form of yellow*

The fact that black and brown pigment is present in agouti animals in a presumably constant degree of intensity and that the yellow pigment may independently vary in these animals from cream to deep red, may possibly serve to explain the marked variations seen in the type known as intense black agouti (golden agouti)

A table showing the result of crossing "creams" (light yellow) *inter se* follows

TABLE I

Parents, "cream" × "cream",
Offspring, "cream" 31, black 10, brown 14
(*light yellow*) (*intense*) (*intense*)

From Table I it will be seen that non-yellow young of a dilute character are not produced by mating cream-colored animals *inter se* On the other hand, such young have been produced by dilute yellows crossed *inter se*, as shown by Table II

TABLE II

Parents, dilute yellow × dilute yellow,
Offspring, dilute yellow 95, dilute non yellow 52.

Further, when dilute yellows are mated with dilute non-yellows the non-yellow offspring are all dilute (see Table III)

TABLE III

Parents, dilute yellow × dilute non yellow,
Offspring, dilute yellow 38, dilute non yellow 37.

In the foregoing account dark-eyed yellows are alone used in computing the numerical results Experiments with pink-eyed yellow forms have been conducted, but the data have not yet been tabulated

DIMORPHISM OF THE GAMETES OF ŒNOTHERA[1]

PROFESSOR DE VRIES[2] has brought to light a

[1] Read before the Botanical Society of Washington, May 2, 1911

[2] "Ueber doppeltreziproke Bastarde von *Œnothera biennis* L und *O. muricata* L.," in *Biologisches Centralblatt*, 31: 97–104, No 4, February 15, 1911.

remarkable form of dimorphism of the gametes of several species of evening primrose If reciprocal hybrids are made between, say, *Œnothera biennis* and *O muricata*, the resulting hybrids are very unlike and strongly patrocline, in both cases presenting only slight traces of any influence by the female parent Detailed investigations now under way by Professor de Vries show that the ovules and pollen grains carry quite different hereditary tendencies The common *Œnothera biennis* represents the form inherited through the pollen, the characters carried by the ovules being recessive If *O biennis* is crossed with pollen of another species over which it is dominant, the result is to bring into expression the form inherited through the ovules, which de Vries calls the *conica* form This form is obtained if *Œnothera biennis* is crossed with pollen of *O muricata*, *O Hookeri*, *O strigosa*, etc Similarly, if *Œnothera muricata* is pollinated with *O biennis* (Chicago form), *O Hookeri* and *O strigosa*, it yields what de Vries calls the *frigida* form which represents the form of *O muricata* inherited through the ovules

The ordinary form of *O biennis* represents what de Vries calls the pollen picture of this species, the pollen form (*biennis*) being dominant over the ovule form (*conica*) The same is true of *O muricata*, the ovule form (*frigida*) being recessive to the pollen form (*muricata*)

This property of producing gametes having diverse hereditary qualities is termed by Professor de Vries "*Heterogamie*," but as this term is already used in many different senses it seems best to propose instead a new term, *allogametism*, after the analogy of such words as allotropism

The pollen grains and ovules of *Œnothera biennis* and *O muricata* would constitute *allogametes*

If B represents *Œnothera biennis*, M, *Œnothera muricata*, H, *Œnothera Hookeri*, and L, *Œnothera Lamarckiana*, the second term being the male parent in each case, some of the remarkable results of allogametism are as follows:

Hybrid BM = *conica* (ovule picture of *O biennis*)
Hybrid MB = *biennis* (pollen picture of *O biennis*)
Hybrid MH = *frigida* (ovule picture of *O muricata*)
Hybrid LM = *muricata* (pollen picture of *O muricata*)

In such allogametic species of *Œnothera* the diversity of the gametes of the two sexes does not become apparent unless reciprocal hybrids are made with another species, whereupon very different results are obtained, depending upon which species is used as the female parent

In case the reciprocal hybrids of the same two parents are crossed, what de Vries calls double reciprocal hybrids result, thus

$$BM \times MB = B,$$
$$MB \times BM = M$$

In such cases the "peripheral"[3] grand parent shows complete dominance, while the "central"[3] grand parent is eliminated, thus

$$B(M) \times (M)B = B,$$
$$M(B) \times (B)M = M$$

If a patrocline hybrid is crossed with pollen of the paternal species, what de Vries calls *iterative* hybrids result, exactly like the first hybrid and very like the paternal species, thus

$$MB \times B = MB = B,$$
$$B \times BM = BM = M$$

The central term in the formula is eliminated in this case, $M(B) \times B = MB = B$

If a patrocline hybrid be crossed with pollen of the mother species, what de Vries calls *sesqui-reciprocal* hybrids result in which the grandpaternal species is eliminated, thus:

$$MB \times M = M,$$
$$BM \times B = B.$$

The central term in the formula is again eliminated, $M(B) \times M = M$

Not all the characters of the species were found to be transmitted allogametically. In

[3] So called from the position in the above formulæ

O biennis and *O muricata*, however, the only exception seems to be in the size and form of the petals

The very interesting discovery was made by J M Geerts[4] that approximately half the ovules and half the pollen grains of the allogametic species of *Œnothera* are abortive It is suggested that in case of *Œnothera biennis* only those ovules that carry the *conica* form develop, those that should carry the *biennis* form aborting On the other hand only those pollen grains which carry the *biennis* form mature, those that should carry the *conica* form failing to develop

WALTER T SWINGLE

STUDIES IN ARTERIOSCLEROSIS

MUCH has appeared in the literature in recent years upon the etiology and process of development of arteriosclerosis Many observations have been made upon the human subject and also in experimental animals, of points co-relating certain factors with the production of disease in the arterial tree In most instances these factors have been carefully studied by competent observers and in many instances the results have been verified by others

The gathering of facts concerning arteriosclerosis is quite simple—the interpretation of these involves much difficulty In carrying out any experiment or in offering reasons for a given result, we are constantly reminded of the manifold factors which enter a given experiment or which are naturally present. Often our experiment on animals only induces altered conditions which indirectly bring about the result we are seeking That the greatest care must be exercised in drawing inferences from animal experimentation is well illustrated in studies upon arteriosclerosis

Recently Levin and Larkin[1] have published the results of their experiments on dogs, in which by producing an arterio-venous anastomosis between the external jugular vein and the external carotid artery, they arrive at the sweeping conclusion that "arteriosclerosis can not be artificially induced in a previously healthy blood-vessel by a change in the blood pressure alone" To *this type* of conclusion we must take exception

Levin and Larkin, experimenting on ten dogs, joined the external carotid artery to the external jugular vein In two of these dogs thrombosis occurred close to the line of suture in the vessels All but two of the remaining eight animals received injections of adrenalin at varying periods These eight dogs, which form the positive results and from which the above positive statement respecting arteriosclerosis was made, were allowed to live 102, 38, 72, 15, 124 and 58 and 44 days, respectively

No one, who has studied diverse pathological lesions, will deny that the distribution of various lesions in organs is not uniform in the animal world Man is particularly subject to lesions of the circulatory system—a condition not so frequent in lower animals Rabbits and horses occasionally suffer from arterial lesions—more often seen in the older animals and in certain breeds Dogs and cats rarely develop lesions in the arteries, even under the most trying circumstances

This varying susceptibility still awaits an explanation, but in the face of our ignorance in the matter, we must assume the greatest care in drawing broad conclusions or in proposing far reaching principles Negative experimental results for the dog have no positive bearing upon experimental facts observed in other animals

Much criticism is offered against the use of the rabbit for experiments upon the circulatory system The comment has been that spontaneous arterial disease occurs in this animal And yet none of the critics offer any suggestion for the cause of this spontaneous lesion! Properly selected animals and controlled experiments can reduce the error of "spontaneous" disease to almost a vanishing point The very feature, in the rabbit, of readily reacting in its arterial tree to different

[4] Geerts, J M, "Beitrage zur Cytologie und der partiellen Sterilibat von *Œnothera Lamarkiana*," in *Recueil des travaux botaniques néerlandais*, 5: 93–208, pl 5–22 (N 2–4, June, 1909), also published as a separate article

[1] *Jour Exper Med*, 1911, XIII, p 24

noxæ, determines its usefulness for studying the diseases of the circulation.

In the experiments of the above-cited authors, the observations were made upon the venous segments of the anastomosis Here although in only some of the animals the vein was noted to be dilated, it is concluded that an increased blood pressure existed in all It is not at all clear to what extent the blood pressure was increased when the external carotid and external jugular were united With the free anastomosis which exists (varying much in individual animals), between the venous channels of the neck, it is possible that an increase of pressure exists for only a short period after the successful anastomosis[8]

It is further to be pointed out that various observers have recorded that periodic and intermittently increased blood pressures have quite a different effect upon the blood vessels than a constant and continuous one The periodically increased pressure is found commonly in man, and if we may draw any conclusions from the finding of occupation sclerosis (right radial sclerosis in the blacksmith, femoral sclerosis in the policeman), it is that the periodic increase of pressure leads to degenerations and sclerosis in the arteries

Finally, but of primary importance, the results of observations on veins can not be utilized in drawing conclusions about arteries, as has been done by Levin and Larkin

PRESENCE OF ARSENIC IN FRUIT SPRAYED WITH ARSENATE OF LEAD

The spraying of fruits with an arsenical has been practised for a number of years in the control of insects which destroy by eating. The form in which arsenic was first used was Paris green, which, however, proved, for the most part, to be more or less injurious to foliage and fruit on account of the soluble character of the compound. Only within recent years has arsenate of lead come into use The main reasons for its use as recommended by entomologists was its greater purity and insolubility in water During the past three years the writer has had occasion to question the use of arsenate of lead as commonly found on the market Many brands do not show sufficient uniformity in arsenic content, nor is the arsenic found in the proper combination with the lead. When lead nitrate and disodium arsenate or lead acetate and disodium arsenate are combined at least three forms of arsenate of lead may result, namely, ortho-arsenate of lead ($Pb_3(AsO_4)_2$), pyro-arsenate of lead ($Pb_2As_2O_7$) and meta-arsenate of lead ($(PbHAsO_4)_2$) The last named compound is very injurious to foliage and fruit under certain climatic influences, and the pyro-arsenate of lead may become so in the presence of water containing soluble chlorides, sulphates or carbonates Very few of the waters commonly used to apply arsenate of lead are pure, hence injury may result, although the compound if used with chemically pure water will produce no injury The ortho-arsenate of lead, however, is practically insoluble in neutral and alkaline solvents

Besides any apparent injury, such as the spotting or burning of the fruit and foliage, a certain amount of arsenic may be absorbed by the fruit without showing any injury at the time The occurrence of certain spots on apples held in storage has occupied the attention of the writer for some time. Upon examination, such fruits were found to contain appreciable quantities of arsenic The badly red-spotted and black-spotted fruits showed approximately twice as much arsenic as fruits from the same lot which showed no spotting. A ten-gram sample of badly spotted apple skin showed 0.05 of a milligram of metallic arsenic. One large Spitzenburg apple showed a total of 0.3 milligram of arsenic calculated as As_2O_3. The fruits were carefully washed so as to exclude from analysis all arsenic that adhered to the surface.

It has also been noted by the writer that certain papers used to wrap apples and pears, a practise common on the Pacific coast, con-

tain, very frequently, small amounts of arsenic, as well as other substances which may or may not have an injurious effect. It is quite well known that small quantities of arsenic have a tendency to hasten the ripening process in fruits One instance of particular interest has been noted A certain shipment of pears was wrapped with two different brands of paper The pears were of one variety, all from one orchard, and were kept under exactly the same conditions and treated in every way the same, excepting that about one half of the shipment was wrapped with one brand of paper and the rest with another brand After the fruit had been in storage for some time it was found that the ripening process in one lot was much in advance of the other, the other lot remained normal After an examination of the whole shipment it was found that the condition of the fruit corresponded exactly with the brand of paper used. It would seem from this that fruit growers should pay particular attention to the quality of paper used for wrapping fruit as well as the quality of arsenate of lead used in spraying the fruit

P J O'GARA

THE AMERICAN PHILOSOPHICAL SOCIETY

THE annual general meeting of the society was held in the hall of the society, Philadelphia, April 20, 21 and 22, at which about sixty papers were presented on scientific and literary topics

President W. W Keen, LL D, and Vice president E C. Pickering took turns in presiding at the various sessions

It has been the custom for several years to devote one half day session to a symposium on some special topic in science This year the subject was "Modern Views of Matter and Electricity," and the following papers bearing on this general topic were offered "The Fundamental Principles," by Professor D F Comstock, of Boston, "Radioactivity," by Professor B B Boltwood, of New Haven, "Thermionics," by Professor O W Richardson, of Princeton, "The Constitution of the Atom," by Professor H. A Wilson, of Montreal. The general conclusion seems to be that the atom of matter, groups of which compose the molecules of different substances, is built up of much smaller parts, known as electrons, identical with the smallest unit of negative electricity Sir J J Thomson's theory of the atom assumes also a spherical form of positive electricity, throughout which are imbedded the electrons in different numbers according to the kind of atom It was also explained how it is possible to estimate the actual number of electrons in an atom of any given kind As the inertia of an electron emitted from the atom of a radioactive substance, such as radium, has been experimentally proved to be a function of its speed, the evidence is strong that all inertia or mass may be electrodynamic in its nature

At the opening session on Thursday the following papers were read

Notes on Cannon Fourteenth and Fifteenth Centuries CHARLES E DANA, Philadelphia

The first absolutely reliable, contemporaneous account we have of cannon is contained in an edict, still to be seen, in Florence, Tuscany, dated 1326 What these cannon looked like or did we shall never know, but with them begins the authentic history of ordnance, back of them is only legend

Powder was in those early days, as its name implies, a dust, it contained the charcoal and sulphur of to day, as well as the saltpeter, but far too small a quantity of the last, on account of the difficulty in procuring it The cost, in the middle of the fourteenth century, was almost prohibitive, cheap at twenty five dollars a pound, in money of to day

The next mention of cannon is of some at the Tower of London in 1338, amongst these were several breech loaders Another, in the same year, called a "pot for hurling arrows," was the pride of the arsenal of Rouen, France The charge for this mighty engine of war was less than an ounce of the badly proportioned dust of that day—termed powder

It is often asserted that three field guns were used by the English at Crécy, where, in 1346, they gained so tremendous a victory One must always remember that a large body of English archers was there present Every man of them was a dead shot, firing ten or more arrows a minute from his "longbow", the effective range was two hundred and fifty yards, every "cloth yard arrow" was an armor piercing projectile. Of what use three absurd pop-guns would have been it is difficult to imagine. The interest is purely antiquarian, as these would have been the first field-artillery mentioned in history. That cannon were

used at the siege of Calais, which immediately followed Crécy, there is no doubt whatever

By the end of the fourteenth century huge bombards, throwing stone balls of two hundred pound weight, were common, later, stone balls weighing a thousand pounds, requiring a gun caliber of over thirty inches, were in use

The quick firing, breech loading guns of the fourteenth and fifteenth centuries, when they were provided with at least four chambers, which chambers looked much like a beer mug and contained the powder charge, could be fired about once in two minutes These were most effective at sea, fired from the tops, just as our quicker firing guns are, they were used for clearing the deck, loaded with bullets, rusty nails and a general assortment of scraps they were worthy of their name—"murtherers"

The great bombards, and many of the smaller guns in the fourteenth century, were built of longitudinal wrought iron bars, over which heavy iron rings or bands were driven The breech, containing the powder-charge, was usually forged, the caliber being about a third that of the chase The powder charge was about one eighth to one ninth the weight of the stone projectile In spite of the smallness of this the bombard had a bad habit of bursting, spreading death in all directions except where it was intended to

The field guns at the end of the fifteenth century would not have looked very strange in, say, 1800 For it must not be forgotten that the guns used by Nelson at Trafalgar (1805) differed but little from those used by Howard and Drake against the Spanish Armada, over two hundred years earlier

The Cost of Living in the Twelfth Century and its Effects DANA C MUNRO, University of Wisconsin

The rise in the cost of living in the twelfth century was due to a change in the standard of living Acquaintance with the east, through the crusades, led to a desire for more costly clothing, and fashion began its despotic sway More luxurious dwellings, oriental spices and other products became common The amount of money available was greatly increased by the coining of the gold and silver which had been hoarded, by the more rapid circulation of the money, and especially by the use of instruments of credit which became common in the twelfth century

An era of extravagance ensued which is well depicted in the literature of the age The average noble was unable to increase his income, which was derived from fixed customary payments Consequently, to meet his new needs he was compelled to borrow at ruinous rates of interest The lender was frequently a Jew and much of the ill will toward the Jews is to be traced to the hostility of the borrowers who were hopelessly in debt

The peasants profited by the opening of more markets for their agricultural products and were sometimes able to gain their freedom by the payment of a small lump sum when the lord of the manor was hard pressed for money The merchants profited most by the increase of trade and became factors in the political life of the day Sumptuary laws were frequent but ineffective

As yet too little attention has been paid to this change in the standard of living and its effects There is a great mass of material in the shape of documents, such as the Pipe Rolls, *e g*, and there are many references in the contemporary literature There is an opportunity and need for a number of students to investigate various phases of the subject This is one of my reasons for presenting this subject here

Moreau de Saint Méry and the other French Exiles Some of our Forgotten Members

One of the results of the French Revolution was that many of the exiles from France and its West India colonies found a harbor of refuge in

Philadelphia, and some of the most notable among them became members of the American Philosophical Society

Talleyrand, Noailles, Chastellux, Rochefoucauld Liancourt, Brissot and Volney are known by their books and by their subsequent career in France

One of the most active in the Philosophical Society was Moreau de Saint Mery, now almost forgotten, but recently rescued from oblivion by the publication of some of the documents from his large collection of 250 volumes, in the *Proceedings* of the Wisconsin Historical Society and the *Canadian Archives*

Born in the island of Martinique in 1750, dying in Paris in 1819, he was employed in the royal government of Saint Domingo, and published a collection of the laws of the French West Indies He sent scientific papers to the American Philosophical Society, and was elected a member in 1789 Driven from France, where he was a member of the First Convention, representing the West Indies colonies, he found refuge in Philadelphia

Here he opened a book store at Second and Walnut Streets, published works of his own on Saint Domingo, one of them translated by William Cobbett, then living in Philadelphia, and his own translation of a book on its prisons by Rochefoucauld Liancourt, and one on China by VanBraam, "of China Hall near Bristol," who had been a member of a Dutch embassy in China, and brought here a large collection of curios from China

Saint Mery printed a catalogue of books in French, German, Italian, Latin and Greek on sale in his book store, which is quite remarkable for its extent at that period His book store was quite a meeting place for other French exiles of all parties, Royalists, Girondins, Jacobins, and he and they were frequent visitors to the Philosophical Society and contributors to its *Proceedings*

Returned to France through the influence of his relative, Josephine, Napoleon gave him in succession important positions, and, as historiographer of the Marine Department, he made the large collection of documents relating to the history of France in America, which is now one of the most important series in the great French Archives

He was a diligent collector, an intelligent observer and a notable character in his day and generation, and his stay in Philadelphia was not without influence on both countries

He followed Talleyrand in guiding Napoleon to sell to the United States the vast and unknown Louisiana Territory, so important in the later history and growth of the United States

When France lost its holdings on the American continent, Saint Mery began to collect historical documents relating to the period when France controlled Canada and Louisiana and disputed with Great Britain possession from the St Lawrence to the Gulf of Mexico

Now in his collection, historical students in Canada and Wisconsin find the material for publication on the history of France in America His zeal for rescuing from destruction these sources of history is now receiving acknowledgment, and his name figures in the works of Aulard and Thwaites, who find in his collection material of great value for their recent contributions to our knowledge of history Apparently a modest man, his service to the American Philosophical Society, his contribution of his own papers and books and objects of interest for its collection, and in bringing to its meetings many of his fellow exiles, were of value Some of his countrymen became members of the society, thanks to his introduction, and among them were those who played a large part in the history of France His own collection of historical documents throws much light on the early French settlements in the United States, and makes the best memorial of his zeal in spreading useful knowledge

The session on Friday morning was devoted especially to botany, chemistry and astrophysics, and the following papers were presented

Study of the Tertiary Floras of Atlantic and Gulf Coastal Plain EDWARD W BERRY, associate in paleontology, Johns Hopkins University (Introduced by Dr J W Harshberger)

The Desert Group Nolineæ (illustrated) WILLIAM TRELEASE, director of the Missouri Botanical Garden, St Louis

The Blueberry and its Relation to Acid Soils F E COVILLE, U S Department of Agriculture (Introduced by Dr J W Harshberger)

Experiments covering a period of five years, with many kinds of soil and nutrient solutions, showed that in all so called fertile soils the blueberry either does not thrive or it dies outright In an acid peaty soil, such as occurs in bogs or sandy woods, it grows luxuriantly Ordinary plants suffer in such soils from nitrogen starvation The blueberry, however, bears on its roots a fungus which appears to act in a beneficial manner by furnishing nitrogen to the plant

On the basis of these experiments the blueberry has now been put into actual field culture on a small scale, with every prospect that it will be

made commercially successful In the field plantings bushes grown from the seed have been chiefly used, but the propagation of superior varieties by layering and by cuttings is now in progress, one of the varieties having berries over half an inch in diameter

The acid lands on which the blueberry grows best are commonly regarded as of little value agriculturally Blueberry culture offers a special means for the utilization of such lands

The blueberry is not alone in its ability to thrive in an acid soil. Experiments with various other plants indicate similar characteristics For example, the wild trailing arbutus, which has been regarded as exceedingly difficult of cultivation, grows luxuriantly when potted in the acid peaty soil found so successful for the blueberry Exceptionally beautiful flowering plants have been grown from the seed in less than two years There is no reason why trailing arbutus can not be added to the choice potted plants of the florists' trade

It is impossible to foretell to what extent other useful plants than the blueberry will be found to be adapted to acid soils The cranberry is clearly an acid soil plant. Dr H J Wheeler, of the Rhode Island Agricultural Experiment Station, has shown that the strawberry, the potato, rye, lupin and buckwheat grow as well or a little better without the use of lime In other words, they are acid soil plants

It is not altogether a dream to foresee the development of a special acid land agriculture, in which the rotations shall include only such crops as prefer an acid soil or are indifferent to acidity

The Solar Constant of Radiation: C. D ABBOTT, Smithsonian Institution (Introduced by Dr C. D. Walcott.)

If we had no eyes we should still know of the sun by the feeling of warmth The most exact measurements of the intensity of the rays of the sun, whether they be visible to the eye or affect the photographic plate or not, are made by an electrical thermometer called the bolometer This instrument is so sensitive that a millionth part of a degree change of temperature is recorded by it For seven years the bolometer has been used by the staff of the Astrophysical Observatory of the Smithsonian Institution to measure the solar constant of radiation This constant represents the number of degrees (centigrade) which one gram of water would rise in temperature if all the solar radiation which could pass through an opening one centimeter square outside the earth's atmosphere, but at the earth's mean distance from the sun, could be used for one minute to heat the water As all life and almost all forces on the earth depend on the supply of solar rays, the solar constant of radiation is at least equal in importance to the knowledge of the sun's distance

The value of the solar constant was unknown within wide limits only five years ago It is now believed to be within 1 per cent of 1 93 calories per square centimeter per minute Measurements made at Washington (sea level), Mt Wilson (one mile elevation and Mt Whitney (nearly three miles elevation) agree in fixing this conclusion

Nearly 500 determinations have been made They indicate that the value is not really a "constant," but fluctuates about the mean just given within a range of 8 per cent This conclusion means that the sun is a variable star. It is hoped soon to verify it completely, and it may prove for meteorology hardly less important than the determination of the mean value of the solar constant itself.

Some Curiosities in the Motions of Asteroids: ERNEST W BROWN, professor of mathematics, Yale University.

Spectroscopic Proof of the Repulsion by the Sun of Gaseous Molecules in the Tail of Halley's Comet: PERCIVAL LOWELL, director of Lowell Observatory, Flagstaff, Ariz.

Self luminous Night Haze: EDWARD E. BARNARD, astronomer, Yerkes Observatory, Williams Bay, Wis.

Some Peculiarities in the Motions of the Stars: W. W CAMPBELL, director of Lick Observatory, Mt Hamilton, Cal.

Taking a Census of the Chemical Industries CHARLES E. MUNROE, professor of chemistry, George Washington University, Washington.

Some Recent Results in Connection with the Power of Solutions to Absorb Light HARRY C JONES, professor of physical chemistry, Johns Hopkins University

The Properties of Salt Solutions in Relation to the Ionic Theory ARTHUR A NOYES, professor of theoretical chemistry, Massachusetts Institute of Technology (Introduced by Dr James W Holland)

The Atomic Weight of Vanadium GUSTAVUS HINRICHS, of St Louis (Introduced by Professor Amos P Brown)

Quinazolone Azo Dyestuffs A New Group of Azo Dyes MARSTON TAYLOR BOGERT, head of School of Chemistry, Columbia University, New York

The Friday afternoon meeting was devoted mostly to geology and to biology

The following papers were read

Shore and Off shore Deposits of Silurian Age in Pennsylvania GILBERT VAN INGEN, of Princeton University (Introduced by Professor W P Scott)

The lithological and faunal characteristics of the Silurian formations were briefly described and the changes in these features were interpreted in terms of their geographic positions in respect of the shore lines and open seas of that time The marine oolitic iron ores of the center of the basin were shown to change in shoreward directions to hematitic sandstones of much greater thickness and finally to red and olive quartzites, which are equivalents of part of the Shawangunk grit of the northeastern Appalachians The conclusion is reached that the Shawangunk grit is of Medina-Clinton Niagaran age and all older than the Salina to which it has lately been referred

Tertiary Formations of Northwestern Wyoming WILLIAM J. SINCLAIR, of Princeton University (Introduced by Professor W B Scott)

Mr Sinclair gave a rapid review of the stratigraphy of the Wind River and Bighorn basins, followed by a discussion of the color banding in the Eocene clays, which he correlated with climatic changes.

On a New Phytosaur from the Triassic of Pennsylvania · WILLIAM B SCOTT, of Princeton University

Alimentation of Existing Continental Glaciers · W. H. HOBBS, of University of Michigan

It was in the Alps of Switzerland that the early studies and by far the larger number of subsequent investigations of glaciers have been made. The Swiss type of glacier is one of the most diminutive, but as the theory of former continental glaciation was derived from these studies of puny glaciers, it is not surprising that their attributes were carried over unchanged to the reconstructed extinct types thousands and even tens of thousands of times larger, and this before any continental glaciers had actually been studied The recent explorations of Norwegian, German, Swedish and Danish explorers, but more than all of Peary in Greenland, and of Scott, Nordenskiold, von Drygalski and others, but especially of Shackleton in Antarctica, have at last afforded us with observations upon the existing continental glaciers When these reports are carefully studied and compared, it is found that as regards their form, their erosional processes, and especially their nourishment and waste, continental glaciers are as different as possible from those of the Alpine type Instead of being nourished by snow precipitated from *surface* air currents which are forced to *rise*, their snow supply is derived from the fine ice grains contained in *high level* cirrus clouds which have been *drawn down* to the glacier surface, been melted, and there reprecipitated This action is the work of a refrigerating air engine which is developed directly by the snow-ice mass itself The paper is illustrated by lantern slides

On the Formation of Coal Beds J J STEVENSON, University of the City of New York.

Two hypotheses, presented to explain accumulation of coal in beds, have been in conflict for almost a century and a half One asserts that the vegetable material was transported by running water and deposited, as were the enclosing sandstones and shales, the other assigns to transport an insignificant share and maintains that the vegetation grew where the coal bed is now found

The disputants agree practically on what may be termed facts of observation, such as the nature of the material and the structure of the beds, but the parting comes in the effort to explain the phenomena by reasoning backward from known conditions of our own time. There is room for surprise when one discovers that phenomena, regarded by one writer as final arguments in support of his hypothesis, are regarded by another as equally final in support of the contrary doctrine. Too often, the reasoning is from the hypothesis to the facts and the *a priori* argument seems to be based on an imperfect knowledge of present phenomena or on a purely local study.

Ten years ago I began systematic study of conditions throughout the vast Appalachian basin, hoping to find there enough information for solution of the problem involved, but the results were far from sufficient and study of other regions became necessary. This required examination of hundreds of publications, large and small—and the examination is still far from complete, for the literature, to speak moderately, is sufficiently extensive and, within the last quarter century, sufficiently intensive. While plodding through it, I discovered that much of what has been regarded as new in later days is really very old. The work of earlier students, buried in publications of learned societies, has passed into oblivion. In some instances, important observations have been recorded incidentally in discussion of other topics. Often, the work of an investigator is known only through citations, which, separated from their context, are apt to give a wrong conception of the author's opinions. As the examination advanced, I became convinced that it would be well to present, without comment, a synopsis of each work that seemed to have an important bearing on the subject, that the development of opinion might be made clear and that proper credit might be assigned to men who did excellent work with meager opportunity. Such a presentation seemed also likely to serve as a proper foundation for the general discussion and it is offered here as the first part of a monograph upon the formation of coal beds.

As the study advanced, the elements of the problem were found to be more numerous and more complicated than had been supposed. It has become essential to consider in detail some subjects of which many of the disputants on both sides appear to have very indefinite conceptions.

The second part of the monograph will consider the flexibility of the earth's crust as illustrated in the history of North America, the phenomena of rain and floods, the features of swamps and marshes, the buried forests of modern and ancient times; with other topics of similar import.

The third part will consider the various deposits of the Coal Measures, sandstones, shales, limestones and coals, the effort will be made to determine the sources and the mode of distribution of the inorganic materials; the origin of the coal and the causes of its variation in character, its mode of occurrence and the structure of coal beds.

The fourth part will sum up the results in an effort to show their bearing on the solution of the problem.

Problems in Petrology: J. P. Iddings, U. S. Geological Survey. (Introduced by President Keen.)

Front Range of the Rocky Mountains in Colorado: W. M. Davis, of Harvard College.

The Front Range of the Rocky Mountains in Colorado, now easily accessible by various railroad lines which enter and cross it from Denver and Colorado Springs, is an unusually fine example of a mountain highland, which in a former cycle of erosion was reduced to moderate relief, and which since elevation to its present altitude has been submaturely dissected by its streams. The highland is surmounted by numerous hills and mountains of from 500 to 2,500 feet relief, which represent the unconsumed residuals of the former cycle of erosion, and which, therefore, presumably consist of the most resistant rocks of the region. The uplift of the mountain belt to its present altitude was not perfectly uniform, but arched gently from the plains westward, thus the crest of the range seems to correspond to the crest of the arched uplift. A notable feature of the higher valley heads, among the surmounting mountains near the range crest, is the occurrence of numerous amphitheaters or cirques, and over deepened valley troughs, the work of glaciers which for a moderate time, as geological time is reckoned, replaced the water streams in the highest districts. The contrast between forms due to ordinary or normal erosional processes and to glacial erosion is thus displayed with unusual clearness.

Supposed Recent Subsidence of the Atlantic Coast: D. W. Johnson, of Harvard College. (Introduced by W. M. Morris.)

The author briefly reviewed the evidence in support of the generally accepted theory that the Atlantic Coast is subsiding at the rate of from one to two feet per century, and showed that the phenomena supposed to indicate subsidence might be produced by fluctuations in the height of ordinary high tides resulting from changes in the form of the shore line. A study of the Atlantic shore line indicates that conditions are there favorable to marked local changes in the height of the tides, independently of any general movement of the land. On the other hand, the structure of certain beaches along the coast affords very strong proof that there can have been no long-continued progressive subsidence of the coast

within the last few thousand years The theory of fluctuating tidal heights, and the theory of stability of the land mass were illustrated by selected examples of shore line phenomena

Relation of Isostasy to the Elevation of Mountains H F Reid, of Johns Hopkins University

The work of many investigators and more especially the recent work of Dr Hayford has shown that the earth is practically in isostatic equilibrium It follows that mountains can not be due to tangential compression or to the increase of matter in the mountains themselves, but must be due to forces of elevation resulting from the expansion of the material under the mountains Such vertical forces would in many cases cause normal faulting without tangential tension

The Transpiration of Air through a Partition of Water Elliptic Interference with Reflecting Gratings Carl Barus, of Brown University

A Phenomenon of Vision On Disruptive Discharges of Electricity through a Flame F. E Nipher, of Washington University

The High Voltage Corona in Air J B Whitehead, of Johns Hopkins University (Introduced by Professor Ames)

The author described the limitation to the long distance electrical transmission of power imposed by the insulating properties of the air, and a new method for determining accurately a voltage at which the air in the neighborhood of electric wires and cables will break down, and also gave the results of a series of experiments on the influence of the size of the wire, the stranding of the wire into a cable, the frequency, the pressure, the temperature and the moisture content of the air He also reviewed the bearing of present physical knowledge on the nature of the phenomena which are involved

The Nature and Causes of Embryonic Differentiation · E. G Conklin, of Princeton University

The Origin and Significance of the Primitive Nervous System G H Parker, of Harvard University (Introduced by Dr H H Donaldson.)

On Friday evening Professor Svante Auguste Arrhenius gave a lecture at the hall of the College of Physicians on "The Physical Conditions of the Planet Mars"

The lecture was followed by a reception.

The speaker called attention to the many similarities between Mars and the earth which have led some to think Mars is inhabited, but gave it as his opinion that later investigations are not favorable to this view

On Saturday morning at 9 30 the society held an executive session, at which candidates for membership were balloted for As a result the following were elected as members of the society George A Barton, A M , Ph D , Bryn Mawr, Pa , Bertram Borden Boltwood, Ph D , New Haven, Conn , Lewis Boss, A M , LL D , Albany, N Y , John Mason Clarke, Ph D , LL D , Albany, N Y , W M Late Coplin, M D , Philadelphia, John Dewey, Ph D , LL D , New York City, Leland Ossian Howard, Ph D , Washington, D C , Joseph P Iddings, Sc D (Yale, 1907), Chicago, Alba B Johnson, Rosemont, Pa , Arthur Amos Noyes, Ph D , Sc D , LL D , Boston, George Howard Parker, S D , Cambridge, Mass , A Lawrence Rotch, S B , A M (Hon Harvard), Boston, Leo S Rowe, Ph D , LL D , Philadelphia, William T Sedgwick, Ph D , Hon Sc D (Yale, 1909), Brookline, Mass , Augustus Trowbridge, Ph D (Berlin), Princeton, N J , Svante Auguste Arrhenius, Stockholm, Jean Baptiste Edouarde Bornet, Paris, Sir John Murray, K C B , F R S , LL D , Sc D , Edinburgh

At ten o'clock the morning session for the reading of papers opened, the following being presented

The Secretion of the Adrenal Glands during Emotional Excitement Walter B Cannon, of Harvard University

The adrenal glands and the sympathetic nervous system are intimately related The sympathetic system innervates the glands, and the glands in turn secrete a substance that affects bodily structures precisely as the sympathetic system affects them The sympathetic system is aroused to activity in states of emotional excitement Examination of the blood of excited animals reveals the presence of adrenal secretion which was not found in the blood before the excitement Possibly the adrenal secretion continues the excited state Possibly also the adrenal secretion caused by emotional disturbances has some of the effects produced by injection of the substance—such as glycosuria and atheroma of arteries Indeed, two of my students, Shohl and Wright, have recently shown that glycosuria can be produced in the cat by fright The suggestion, however, must be put to further experimental test.

On the Coagulation of Blood · W. H. Howell, Johns Hopkins University.

The theory of the coagulation of blood most commonly accepted at the present time holds that

three of the four necessary factors in the process are present in the circulating blood, but that this fourth which initiates the process in shed blood is furnished by the tissues outside the blood or by the disintegration of corpuscular elements in the blood itself. This fourth factor is an organic substance of the nature of a kinase which in conjunction with the calcium salts of the blood serves to activate the prothrombin, also present in the blood, to thrombin The thrombin then acts upon the fibrinogen and converts it to fibrin, which constitutes the essential phenomenon of clotting In opposition to this theory the author gave experimental evidence to show that in normal blood the fluidity is due to the constant presence of an antithrombin, and that in shed blood the tissue elements furnish a substance, thromboplastin, which neutralizes the antithrombin and thus allows clotting to take place In the vertebrates below the mammals, the thromboplastin is furnished by the cells of the outside tissues and without their cooperation clotting would not occur In the mammals thromboplastin is furnished by elements in the blood itself, the platelets, so that the blood may clot promptly without cooperation on the part of the outside tissues In human beings the condition known as hemophilia, in which there is delayed clotting and danger of fatal hemorrhage, the defect is due not to a lack of kinase in the tissues as a whole, the view usually taught at present, but to an excess of the antithrombin normally present in the blood.

Abnormal Forms of Life and their Application: ALEXIS CARREL, of the Rockefeller Institute.

The author stated the results of some remarkable experiments on the tenure of life in certain tissues when removed from the body and kept in cold storage

The Cyclic Changes in the Mammalian Ovary: LEO LOEB, of the St Louis Skin and Cancer Hospital.

In the mammalian ovary cyclic changes of a very far-reaching character take place They concern the follicles, corpora lutea and ova. There exists in the ovary a mechanism (in the corpus luteum) regulating those changes The corpus luteum prolongs the sexual cycle not by retarding the maturation of the follicles, but by preventing the rupture of the mature follicles My recent observations make it very probable that a partial parthenogenetic development of some ova accompany these cyclic changes in the follicles in a certain percentage of animals.

The Origin of the Porpoises of the Family Delphinidæ F W TRUE, of the U. S National Museum, Washington, D C.

Among the fossil remains of cetaceans obtained a short time since by the National Museum from the Miocene formation of Maryland, is a nearly complete skeleton of a porpoise, which, on examination, proves to be a delphinoid form, that is, a species which may be referred to the family Delphinidæ, but has tuberculate teeth This important specimen enables us to solve, in part, the hitherto unsolved problem of the origin of the typical porpoises of to-day. It now appears unquestionable that they were derived from forms having teeth with tuberculate or serrate crowns, rugose enamel, and anterior and posterior longitudinal ridges This form of teeth is indicated in the recent delphinoid genus *Stano,* in which the crowns have rugose enamel, and, as I have lately discovered, traces of anterior and posterior ridges.

An Ancient Protest Against the Curse on Eve: PAUL HAUPT, of Johns Hopkins University

In the biblical legend of the fall of man, which symbolizes the first connubial intercourse, the Lord pronounced a curse on Eve, saying, "I will greatly multiply thy sorrow and thy sighing In pain thou wilt bear children Nevertheless, thy desire shall be to thy husband, and he shall rule over thee" (Genesis 3·16)

We all know what the forbidden fruit in the Garden of Eden means He who eats of it loses his child like innocence, his eyes are opened; just as Adam and Eve perceived that they were naked. Not to know good and evil, that is, what is wholesome and injurious, means to be like a child.

We find this phrase in the eighteenth book of the Odyssey, verse 228 In the Bible it is used also of the second childhood Barzillai of Gilead answered David, when the king asked him to follow him to Jerusalem, "I am this day fourscore years old, and can no longer discern between good and evil"—that is, My intellect is impaired by old age, I have become again like a child.

An ancient protest against the curse on Eve in Genesis 3:16 is found in the story of Cain and Abel, where we read, "And unto thee shall be his

desire, and thou shalt rule over him" The story of the fall of man and the story of Cain and Abel were, it may be supposed, written in parallel columns.

The author of the ancient protest against the curse on Eve (who may have been a woman or a man under the influence of a woman, a species of genus *Homo* which is common) wrote this "suffragettie" gloss on the space between the two columns. Afterwards it crept into the text of the column containing the story of Cain and Abel The introductory verse connecting Cain and Abel and Adam and Eve is a subsequent addition The name Cain is explained there (Genesis 4 1) as being connected with the verb "canah," to produce When Eve bare Cain she said, "I have produced a man as well as the Lord Just as the Lord formed me from the rib He took from Adam, so I have produced now a new human being"

Some people think that when the Lord created Eve he took not only a rib from Adam, but his backbone Most of us have all our ribs If man eats his bread in the sweat of his face till he returneth unto the ground, and if woman bring forth children born to suffer, it is due to the forbidden fruit Schiller says the fabric of the world is held together by hunger and love

Theories of Totemism E WASHBURN HOPKINS, Yale University

He considered first the definition of totemism and the necessity of understanding the different religious systems which go by the name of totemism He showed that totemism must be disentangled from various accretions which have grown up with it before it is possible to discuss the essence of true totemism When this is done, much that has affected and even produced some of the theories falls away and at the end a comparatively simple belief is revealed which has been built up into various sorts of totemism, so that it is unnecessary to assume a graded and uniform growth in every kind of totemism Apparently later stages may come comparatively early The latest theory of Frazer was examined and compared with that of Lang and that of Wundt Besides this analysis and critique of older theories a new contribution to the theory of utility was made by the presentation for the first time of matter drawn from Sanskrit texts in which practically the same view is represented as that held by the ancient troglodytes Apart from some variations the most common direct cause of totemism is economic rather than religious and then blends with other religious factors, but is not so fundamentally, though there are forms of totemism which are based on religious conceptions and helping to its spiritualistic development

The New History J H ROBINSON, of Columbia University (Introduced by Professor Cheyney)

Eggettes a Conservation of Fuel R P FIELD, of Philadelphia

This paper dealt briefly with the general subject of the utilization of slack coal by manufacturing it into small briquettes, which are called eggettes, and showed that a binder which does not contain pitch or any kindred material is preferable for household use, and that by actual test the eggettes under consideration are cheaper than either anthracite or bituminous coal in the regular sizes, crushed coke, wood, oil or gas There was then given a brief description with lantern slides of the machinery used to manufacture these eggettes, and a few statistical tables

On Saturday afternoon besides the symposium and the papers in connection with it already mentioned a portrait of Thomas Hopkinson, first president of the American Philosophical Society, was presented by Leslie W Miller, principal of the School of Industrial Art, Philadelphia, also an obituary notice of Professor Jakob H van't Hoff, by Harry C Jones, of Johns Hopkins University

At the annual banquet on Saturday evening about one hundred members and guests were present, the president, Dr Keen, presiding Toasts were responded to as follows "The Memory of Franklin," by President Schurman, of Cornell, "Our Universities," by Count von Bernstorff and President Hadley, of Yale, "Our Sister Societies," by Professor W M Davis and Sir John Murray, "The American Philosophical Society," by Professor E C Pickering

Thus ended one of the most successful meetings in the history of the society

ARTHUR W GOODSPEED,
Secretary

SOCIETIES AND ACADEMIES

THE WASHINGTON ACADEMY OF SCIENCES

THE seventy second meeting of the Washington Academy of Sciences, a joint meeting with the Washington Society of Engineers, was held in the salon of the steamer *Southland* the evening of April 28, 1911, while en route from Washington to Norfolk, Va, President F W Clarke, of the academy, presided

A symposium on the Dismal Swamp had been

requested, and the committee on meetings decided to include an excursion to the swamp itself and to have the technical papers presented during the first stage of the trip This plan proved to be eminently practicable, and there is every reason why similar plans that bring people so pleasantly together should be more frequently adopted by scientific societies, for, after all, it is personal acquaintance and private discussion that count for most in such organizations

The first paper of the evening was by Mr E W Shaw, who described the "Geography and Geology of the Dismal Swamp" The various plateaus and old shorelines of eastern Virginia were pointed out and their formation explained The swamp is of recent origin, geologically speaking, and in general is well understood, though the existence of a lake near its center is a distinct puzzle, for the solution of which several more or less plausible theories have been advanced

The second speaker, Dr. C A Davis, discussed "Peat Deposits," a subject of which he is a, if not the, recognized master It was explained that the Dismal Swamp is a great coal field in the making, that it is covered with a layer of peat as much as fifteen feet thick in places, and that portions of this might even now be valuable as fuel

The next paper was by Mr. R Zon, whose subject was "The Forest Types in the Dismal Swamp" After a few introductory and general remarks on the relation of forests to climate and soil, the speaker described in greater detail the principal trees of the swamp, especially the cypress and the black gum.

Mr. F V Coville gave an interesting account of the "Plant Life in the Dismal Swamp," and made his many listeners anxious for the morrow when they were to see for themselves the yellow jasmine in bloom, the dense cane brakes and the many other wonders of plant life in their native jungle

Dr. F. W True told of the "Ground Animals of the Swamp" As these are not numerous, consisting mainly of musk and other rats, swamp rabbits and the like, the speaker so widened his talk as to include fishes, of which there are many varieties, bears, of which there is an abundance; and snakes, of which there is said to be a superabundance.

The last speaker of the evening, Dr. C. Hart Merriam, had for his subject, "The Birds of the Swamp." But as snake stories seemed to take unusually well, and as birds are only feathered reptiles, Dr Merriam began his talk with an account of certain varieties of snakes that abound in the Dismal Swamp—rattlesnakes, copperheads, water moccasins, king snakes, black snakes, water snakes and just plain snakes Having disposed of the snakes, the speaker next described the large variety of birds that have been found in the swamp, and so painted their beauty that, for the time being, even the snakes were forgotten

From Norfolk, Va, the entire party of about 135 was taken into the swamp and even to Lake Drummond, as the guests of and on boats especially provided by the Lake Drummond Canal and Water Company

Many returned to Norfolk the same day, while others camped out near the banks of the lake and returned to Norfolk the following day.

In every particular the excursion was a delightful one, due to the unusualness and the beauty of the place visited, to the exceptional courtesies, including even a complimentary luncheon, of the Lake Drummond Canal and Water Company, and to the untiring supervision of the genial David T. Day, who not only planned the details of the trip but also secured their execution without a single hitch

W J HUMPHREYS,
Secretary

THE PHILOSOPHICAL SOCIETY OF WASHINGTON

THE 695th meeting was held on May 6, 1911, Vice president Fischer in the chair Two papers were read:

Simple Ammonia Apparatus for Temperatures to Minus 70° Centigrade: PROFESSOR C F. MARVIN, of the U S Weather Bureau

The apparatus described and exhibited by the speaker was designed for general laboratory work wherever a liquid bath maintained at the desired low temperature could be made to answer the purpose

The apparatus consisted of a large cylindrical copper tank about 11 inches in diameter and 18 inches high This was jacketed all around, except on top, with thick wooden walls and an interlining of animal hair felt. Inside the copper tank was placed a ring-shaped iron ammonia flask made up of two short sections of standard iron pipe having annular heads at each end. The flask measures about 10 inches in diameter outside by 9 inches high, and 7 inches across the ring inside The flask is supported centrally on three lugs inside the tank, and is provided with a suitable outlet pipe and valve at the top.

In use the tank is filled with alcohol or non-freezing liquid (about 3½ gallons), and the flask charged (two thirds or more) with liquid ammonia (5 to 6 pounds). To lower the temperature, gaseous ammonia is allowed simply to escape slowly from the flask The fumes may be led into a vessel of water with the formation of aqueous ammonia, or allowed to escape entirely A strong circulation of the liquid of the bath is maintained by means of an efficient form of motor driven stirrer

The temperature can be lowered to —25° to —30° C., by the spontaneous evaporation and escape of the ammonia For still lower temperatures it is necessary to use a suction pump to increase the evaporation by reduction of pressure A simple hand pump was described for this purpose with the novel feature that the outlet valve opened directly into a water jacket space supplied with running water Moreover, the valve itself had a small hole directly through it, so that water constantly leaked into the pump chamber and these absorbed large volumes of gaseous ammonia. When in operation, the object of working the piston of the pump up and down is quite as much to expel the water leaking into the pump chamber as to take off the gas, large quantities of which are absorbed by the fresh water entering the pump after each stroke

An apparatus of this character has been used for many years at the Weather Bureau in the comparison of thermometers and other low temperature work, and was first described in Annual Report of the Chief Signal Officer, 1891–92, p. 355. The bath can readily be lowered to —40° C, and thermometer comparisons carried on over a period of four or five hours with an expenditure of not over five or six pounds of ammonia, which costs about $1 50 Experience demonstrates that in a small apparatus of the kind described, it is much more convenient and economical to let the ammonia escape after evaporation than to try to recondense it back to the liquid state. It proves to be quite practicable to carry the temperature down to —70° C, at which a number of thermometer comparisons have already been made

Recent Gravity Work by the Coast and Geodetic Survey: WM. BOWIE, of the Coast and Geodetic Survey.

This paper gave an account of the gravity work done by the Coast and Geodetic Survey during the past few years In 1891 the survey began the use of two sets of half second pendulums which proved efficient and accurate in this relative determination of gravitation, using the gravity pier at the Coast and Geodetic Survey Office as the base station As first constructed the knife edges were fastened to the head of the pendulum with the supporting planes on the pendulum case Several years later this method was reversed, the planes being placed in the pendulum head and the knife edges on the case This gave a more invariable length of the pendulum, as the effect of any wear on the planes would be negligible

The different apparatus used in making the observations were illustrated by lantern slides Previous to 1909 the relative value of the intensity of gravity had been determined at forty seven stations in the United States In that year a campaign of gravity work was begun and is still in progress It will probably close at the end of the present year During the past two and one half years fifty six stations have been established By the end of this year the intensity of gravity will have been determined at about twenty additional stations This will make a total in the United States of about one hundred and twenty stations

The apparatus and methods are sensibly the same as those used in previous work except that an interferometer was used for determining the flexure of the pendulum case due to the horizontal force applied by the swinging pendulum This took the place of the static method The interferometer had never been used previously in any country for determining flexure on the field

In 1909 J F Hayford, the inspector of geodetic work in the Coast and Geodetic Survey, made an investigation of the effect of topography and isostatic compensation on the intensity of gravity, using fifty six stations in the United States He read a paper showing his results at the meeting of the International Geodetic Association at Cambridge and London in that year By the application of the theory of isostasy the large anomalies between the theoretical and actual value of gravitation by the Bouguer and free air reductions were greatly reduced. The mean anomalies without regard to sign for the fifty six stations were 064, 027 and 015 dyne for the Bouguer, free air and Hayford methods, respectively

An analysis of the anomalies by the new method showed that there is only a slight, if any, connection between the size and sign of the anomaly and the character of the topography surrounding the station

The results from this investigation confirm the conclusions arrived at by Mr Hayford in his two investigations of the figure of the earth and isostasy He and the speaker have nearly completed an enlargement of this investigation, using eighty-nine stations It is expected that the results of this investigation will be published by the survey during the coming year This investigation will verify the conclusions arrived at from the preliminary one The work done by the Coast and Geodetic Survey proves that a close approximation to the condition of complete isostasy exists

(The abstracts of the above papers are by their authors)

R L Faris,
Secretary

THE AMERICAN CHEMICAL SOCIETY
NEW YORK SECTION

The eighth regular meeting of the session of 1910–11 was held at Rumford Hall on May 5 Professor Chas Baskerville in the chair

Resolutions were offered on the death of Mr Bernard G Amend

The day of the meeting marked the centenary of the birth of John W Draper and a committee was appointed to consider some fitting memorial celebration

The following papers were presented

"A Tetracetyl Glucosamine Glucoside," M L Hamlin

"Studies on Amylase III Experiments on the Preparation and Properties of Pancreatic Amylase," H C Sherman and M D Schlesinger

"The Lactic Acid Ester of Santalol and other Santalol Compounds," Frederick S Mason

"Electric Tube Furnaces with Calorite Resistors for Laboratory Use," S A Tucker

"A New Rapid Method for the Determination of Manganese in Iron and Steel," F. J Metzger and L E Marrs

"The Oxidation of Ferrous Salts," Chas Baskerville and Reston Stevenson

"Contributions to the Chemistry of Anesthetics III Nitrous Oxide," Chas Baskerville and Reston Stevenson

C M Joyce,
Secretary

THE TORREY BOTANICAL CLUB

The meeting of March 29, 1911, was held at the museum building of the New York Botanical Garden at 3 30 P M Vice-president Barnhart occupied the chair. Thirteen persons were present

The following communication from Miss Caroline C Haynes was then read

Sixteen East Thirty-sixth Street,
New York City.

Mr Bernard O Dodge,
Secretary and Treasurer,
Torrey Botanical Club, Columbia University

Dear Sir It is desired by a number of the members of the club and by others interested, to establish a fund in memory of the late Professor Lucien Marcus Underwood, the income of which may be used to aid in the illustration of the Club's publications It is hoped that this fund may reach at least $5,000.

I ask that you obtain from the club its consent to administer such a fund, and enclose my check for $100, as an initial subscription drawn to the order of the Torrey Botanical Club.

Sincerely yours,
(Signed) (Miss) Caroline C Haynes
February 15, 1911

Dr M A Howe made a motion that the club establish a Lucien Marcus Underwood fund, the income of which shall be used in illustrating the publications of the club, and that the secretary be instructed to convey to Miss Haynes the hearty and appreciative thanks of the club for her generous initial subscription The motion was unanimously adopted

The resignations of Elizabeth Billings, Alice Knox, W L Sherwood and Rev L T Chamberlain were read and accepted

Dr H H Rusby reported having received several acceptances to his invitations to become sustaining members of the club

First on the announced scientific program was a paper on "Virginia Fungi" by Mr. B O Dodge After reviewing the literature relating to Virginia fungi the speaker gave a report on the fungi collected on the estate of Mr. Graham F Blandy at White Post, Clark County, Va., last September.

The second number on the program was on "A Little known Mangrove from Panama," by Dr. M. A. Howe The mangrove in question, *Pelliciera Rhizophorae*, a member of the Tea or Camellia Family, was found in association with *Rhizophora*, *Avicennia*, etc, near the Pacific terminus of the Panama Canal Specimens and photographs were exhibited A description and discussion of this mangrove will appear in the April number of the *Journal of the New York Botanical Garden.*

B O. Dodge,
Secretary

THE SPIRIT OF ALCHEMY IN MODERN INDUSTRY

NEVER in the history of the world has there been such a time of intense human activity as the present never a time of such gigantic undertakings, such marvelous achievements Notwithstanding, the curve of progress is still an ascending one, although for some nations it has run parallel to its axis for many centuries, yet nowhere on the earth is there not at present a marked break in the line which for so long has represented a monotonous level in human affairs

While there has been remarkable progress in ethics, culture and the fine arts, this world movement in human endeavor is epitomized in the expression "modern industry" Of the many factors which have entered into the advance in industry as a whole, possibly the most important is found in the manufacture and use of power Where once we measured results by what a man could do, or later what a horse could do, now we measure the power at our command by thousands of kilowatts We have had an age of steam, and we are passing through an age of electricity, and what next? Many think it will be an age of unprecedented chemical development We have reason to be well satisfied with our present achievements, we do things so much more quickly and on so much larger a scale than our ancestors did But at this enviable rate we can see the end of our resources—coal, timber, iron ore, are already measured in years We must improve our present methods We must inaugurate along every line of great endeavor a systematic search for new

truths, new light into the secrets of nature in order that we may live and work more efficiently

It may seem a long step from a consideration of human dynamics at the intensity of the present, to the work of the alchemists of centuries ago, with all their magic and mysticism, their solitary lives and cherished secrets But in reality there is something in common between these ancient investigators and the leaders in modern industry, and in looking ahead as to how we can best utilize the possibilities of the future we may learn something by considering the mistakes of the past

The captains of industry and their army of co-workers are still alchemists at heart, they still strive to transmute the base materials of the earth into gold But where the alchemist was satisfied only with seeing the noble metal glittering in his alembic, the modern business man is content in obtaining from his still a treasury certificate It requires no magic philosopher's stone to effect a transmutation of paper into gold when once the former bears the proper inscription Wherein have modern methods of alchemy changed from those of that eminent scholar who bore the name Phillipus Aureolus Theophrastus Bombastus von Hohenheim, and who lived and worked in the twelfth century and an account of whose checkered career has been handed down to us?

The spirit of alchemy is well represented in the word itself. It is an Arabic prefix, and the old Latin word for Egypt, meaning the dark, secret or hidden It was the black art of the ancients Another name sometimes used was "hermetic art," meaning also closed or sealed from view. The goal of those men from the gray of antiquity to the monks of the middle ages was the discovery of a way to make gold and silver from the metals already known, such as mercury and copper, tin and iron We can see as we look back over their labors how now and again they received just the encouragement necessary to keep alive the embers of hope which glowed in each one's primitive laboratory By melting the base metal copper with an earth which we now know carried arsenic, a silver white metal was formed, how easy to believe that this was an impure silver which needed but refining to be the longed-for result When iron was left in a water solution of blue stone it disappeared and copper was found in its place Surely this was a transmutation of iron and copper Why not under proper conditions a further change of copper into gold?

But very many patient and able men devoted their lives to this fruitless search without material progress being made The alchemists of Arabia and early Germany were little wiser than their predecessors of Egypt many centuries before them. The explanation of this lack of progress is to be seen in the profound secrecy which was at all times maintained When some enterprising worthy did take it upon himself to transcribe for future generations his knowledge of the mystic art, his sentences were so ambiguous, and his diction so involved, as to make the whole entirely meaningless Mysterious symbols were employed to render imitation the more difficult

There was, therefore, no accumulation of knowledge or experience, and each succeeding investigator continued to grope in the darkness which had ever enveloped his calling, without deriving any benefit from the labor of either his predecessors or his contemporaries The great and insurmountable obstacle to progress was nothing more than the jealous secrecy engendered by selfish competition. Both confidence and cooperation were entirely wanting.

Each one feared that his neighbor might profit by his experience were it to become known, never realizing that he must in the end get much more in return than he gave. There was but one of him, while there were many of his neighbors.

But in the thirteenth century there came a change. One Roger Bacon, who from his rare accomplishments and erudition was called Doctor Mirabilis, and who firmly believed in the existence of the philosopher's stone, was being tried at Oxford for sorcery. To disprove the charges against himself, he wrote a celebrated treatise with a long Latin name, in which he showed that phenomena which had been attributed to supernatural agencies were in fact due to common and natural causes. He pointed out further in his brief, a possible distinction between what he called theoretical alchemy, or work which could advance the knowledge of natural phenomena, and practical alchemy, or the striving after immediately usable information. He is to be regarded as the intellectual originator of experimental research, and by his generous treatment of the knowledge gained, gave to the movement the impetus for which it had so long waited. The limitations of this paper preclude my following in any detail the development of chemistry through the succeeding centuries, but it can be easily shown that just as knowledge was sought after for its own sake, and in proportion as there was free and honest intercourse between the investigators of the time, just so rapidly was real progress made.

The course of human events has been compared to a pendulum. We tend to swing to extremes, to go too far first in one direction, and then in the other, when real progress lies in the middle. The period of alchemy represents the pursuit of science for selfish and sordid ends, its sole object was that of making gold. The pendulum was at one extreme of its path. But at that time, as at this, the making of gold by whatever means did not in itself bring happiness or contentment, or even success. With the appearance of men who took an absorbing interest in the study of natural phenomena, for the purpose of gaining a deeper insight into the world around them, when investigations were undertaken from a desire to know, and to acquire knowledge which could become the property of the world at large, the pendulum began to move back.

For years the efforts of investigating minds were devoted to the explanation of the phenomena of nature, to the discovery of new laws and principles, to the accumulation and organization of facts, into what is called a science—to a real search for truth. This resulted in a general uplift of humanity, an advance in civilization, which can not be described or measured in words. It was a time when the human mind was struggling to determine realities in the midst of tradition and superstition, to realize that nature is always complex but never mysterious, that dependence should be placed in proven facts rather than the vagaries of priests and philosophers. Man became intellectually free.

But for many years after the broad generalizations upon which modern chemistry is founded were well established, industry did not profit much by scientific work. One hundred years ago the men who smelted the iron and copper, the lead and zinc, knew little of the principles underlying their practise. Leather was tanned, woolens and silks were dyed, porcelains and glass were made, without the aid of those who alone knew the chemistry involved. These were times when the advance in chemical knowledge was far ahead of the industries on the success of which

our material comforts depend, and which then stood in such need of help

A rational attempt to apply chemical knowledge and methods to the industries commenced about 1850, and is in reality contemporaneous with the founding of the Institute of Technology which we to-day celebrate It was in 1856 that Perkins made the first synthesis of a coal-tar color, and founded the industry which has become the most remarkable example of applied chemistry that we have In 1855 Bessemer introduced his revolutionary process for making steel, made possible by the clear understanding of the nature of steel through improved analytical processes With the founding of the Institute of Technology and other similar institutions, which not only did its part in advancing science, but taught its students how to apply this science to the problems of the day, our industrial progress has gone forward with leaps and bounds

I would point out in passing that a great contribution in the aid of civilization is not necessarily made by the simple discovery of a scientific fact Although, for example, the reactions underlying the ammonia-soda process were well known for many years, this knowledge did not benefit the world until the genius of Solvay made through it pure and cheap soda available Cavendish long ago discovered that an electric arc produced nitric acid from the air, the world waited until a few years ago in order to profit by this knowledge, when the researches of Birkeland and Eyde made of the idea an industrial process It was for this ability to apply scientific facts to the necessities of the times, that the world was looking at the time of the founding of the Institute of Technology. Much pure science we had, but it was as yet largely "uncontaminated by the worship of usefulness," if I may quote a contemporary. It was to just the kind of men which the Institute of Technology turned out—men who could appreciate the beauties of pure science, and at the same time had the ability to apply it, that our marvelous advance in material prosperity was due.

But to-day there can be seen evidences of a swing of the pendulum past the center, and again to approach an undesirable extreme Research has become a word to conjure with Private bequests for institutions of research in almost every field of science are made in units of millions of dollars The most significant movement, however, is the very general establishment of laboratories for research, and especially chemical research, by great industrial organizations This movement is but in its infancy, and it is here that a return of the old spirit of alchemy is to be feared It has its foundation in the impatience of the more enterprising firms to wait for scientific facts and principles to be discovered by others, hence their willingness to appropriate often very large sums of money and to actively enter the field of what is called research in applied chemistry

From what has already been said, there may appear to be a paradox in the expression "research in applied chemistry" How can the element of research enter into the work of applying to definite ends the facts already established as true by others? Is there a difference between research in so-called pure chemistry, and research in what, for want of a better name, we will call applied chemistry. Possibly I can make the distinction clear by a rough analogy. The development of research in a science may be compared to the exploration of a new country. New roads are to be laid out, tunnels bored and bridges built, in other words, new problems solved. This may be done in two ways First, constructive work may be

undertaken wherever an interesting problem presents itself, without regard to whether there is a demand for such structure or not It is built because of the interest of the builder in solving this particular difficulty, and the pleasure he takes in it, knowing also that some time it will be utilized As a rule he is under no great pressure to get the structure completed This may represent the method of pure chemistry, and the great advance in scientific knowledge of the past was made by boring just such tunnels and building just such bridges The industries have used these structures when they could, or when some second builder could adapt them to use Research in applied chemistry differs from that just described only in this—I should say, it *needs* differ only in this—that when a problem is to be solved, a bridge to be built, the work is undertaken at a point where there is a demand for its use, where people are waiting to cross over so soon as it is finished The method of building is no different, the difficulties no less The fact that the bridge is to be used makes the work of building no less dignified, nor is it possessed of less pleasure In both cases the builder profits by all that has been done before, and contributes his bridge and the new materials of construction he may have found, to those who may come after him To cite an example from experience, suppose I determine the electrical conductivity of metallic oxides at high temperature with great accuracy, and publish the results without reference to any particular application of the data This is pure science But suppose I am trying to perfect an electrical heating unit for high temperatures, and in insulating my resister I do this identical piece of work, namely, measure with great accuracy the electrical conductivity of metallic oxides at high temperature, and again publish the results This is applied science The work need not differ in the least degree It can be as accurately done and the conclusions as scientifically drawn The mere fact that the data will be used for some practical end need not make the work any less purely scientific

Why then has research in pure chemistry commanded more respect than research in applied chemistry? Why did an eminent writer a few months ago lament the fact that there is not more research "uncontaminated with the worship of usefulness"? Why does usefulness contaminate? I think it lies in this the investigator of pure science works in the broad daylight, throws his product open for inspection, and invites all to come and use it when they can In applied chemical research the spirit of alchemy tends to creep in The builder keeps his materials of construction, and his designs, a secret, and so boards up his bridge that those who cross over it can not see how it was built, nor profit by his experience The moment a thing becomes useful we become jealous of its possession, we become narrow in our horizon, we sell our scientific birthright for a mess of potage, we become alchemists

There is a heavy moral obligation on the part of large industrial organizations having fully equipped research laboratories, to contribute their share to the advance of the world's knowledge They have well-stocked libraries, and are provided with all the current periodicals, they profit by all the scientific work which has been done and is being done This is as it should be, and such firms are to be commended for their progressiveness But is this not a reason why such laboratories should do their part in adding to the sum of available knowledge? There is in every laboratory much work which could be published and yet conserve the interests of the corpora-

tion First there are the results which may not have proved valuable to the laboratory in which they were obtained, but which would be of immense value to some one else working in an entirely different field Second, there are those results of value to the laboratory possessing them, but which could be published in an unapplied or "pure" form and which would make an important contribution to science and at the same time the publication would work no injury to the company or corporation most interested And finally there are those results of operations and processes, machines and apparatus, which, if the truth were known, are possessed by a large number of concerns, but are held as valuable secrets by each Every one would profit and no one be the loser by so far-sighted and generous a policy Germany is very justly held up before us as a shining example of marvelous industrial progress and prosperity A very great deal of the credit for her present position is due to her splendid educational system But no small factor in her national progress is the helpful attitude which her industrial organizations take toward the publication of scientific data The individual does not suffer, while Germany both from a purely scientific and an industrial standpoint is rapidly advanced But too often with us the president and his board of directors are alchemists; they fail to see why, if they pay the salaries of their research men, they should give to the public, or their competitors, any part of their results They exclaim "what has posterity done for us?" They would have their laboratories remain the secret chambers of the alchemists, and continue to improve their methods of changing baser materials into gold without regard to the obligations which they owe to their fellows.

It requires no extensive mathematical calculation to prove that the manufacturers themselves would be the ones to profit by such a liberal treatment of the results of scientific work Of one hundred manufacturing concerns each one would give but one per cent of the whole contribution, while he would receive the remaining ninety-nine per cent He could not in the long run be the loser But of vastly more importance, he would feel and know that his organization was taking part in a world movement toward that increase of human knowledge upon which all real progress depends Why become selfish and sordid so soon as one's scientific work becomes of immediate value to one's fellows? The greater sense of satisfaction, the greater success even of an industrial organization, lies in a fuller, freer, more generous publicity of the scientific results of their laboratories Would that each such industry might benefit by the experience of Solomon, King of Israel, who, when asked, "What shall I give unto thee?" replied, "Give me knowledge and wisdom," and he was answered, "Wisdom and knowledge are granted unto thee, and I will give thee riches and wealth and honor"

APPROPRIATIONS FOR THE DEPARTMENT OF AGRICULTURE[1]

THE growth of the National Department of Agriculture during the past ten years has far exceeded that of all of its preceding history This was pointed out by Hon Charles F Scott, chairman of the House Committee on Agriculture, in submitting the new agricultural appropriation bill last winter Its growth as marked by a decade has been phenomenal, viewed either from the standpoint of its scope and authority, its material resources, or its personnel.

[1] From the *Experiment Station Record*, April, 1911

As a full-fledged department with a cabinet minister at its head, the department dates only from 1889. But if we go back to 1839, when $1,000 was appropriated for "agricultural statistics," and include every dollar appropriated out of the treasury of the United States for agricultural purposes down to and including the year 1900, the total sum is, as Mr Scott pointed out, only $45,102,616, while the aggregate of all the money appropriated from the end of 1900 to the end of the current fiscal year reaches a sum nearly double this, or $90,012,058. For the fiscal year 1901 the appropriation for maintenance was $3,304,265.97. This year the department has at its disposal $15,470,634.16. "Ten years ago the total number of persons employed in the department was 3,388, this year if all the rolls were called an army of 12,480 men and women would respond."

Under the bill which the committee submitted, and which after considerable discussion and amendment received the signature of President Taft March 4, provision is made for an even greater development during the ensuing year. The aggregate amount carried by the act is $16,900,016, which by far exceeds that granted in any previous measure, and is $887,050 in excess of the estimate submitted by the department.

There is an apparent increase over the appropriation act for 1911 of $3,412,380, but of this $720,000 is only nominal, since it merely replaces what has hitherto been provided automatically as a permanent appropriation to the state experiment stations under the Adams Act. It will be recalled that by the terms of that act as subsequently construed in the appropriation act for 1907, definite appropriations were made only until July 1, 1911. The action taken by congress now provides for the continuance of the Adams Fund on the same basis as the Hatch Fund, requiring the amounts to be appropriated annually in the agricultural bill. With due allowance for this item, however, there is still an actual enlargement of the appropriations of every bureau, and a net increase of fully 20 per cent. for the department as a whole.

In general the increased appropriations are for the purpose of extending and developing lines of work already under way rather than the undertaking of new projects, and some of the principal increases are for what may be termed the administrative activities of the department. One of the largest new items is an appropriation of $1,000,000 for fighting and preventing forest fires in the national forests in cases of extraordinary emergency. This appropriation is in addition to the regular appropriation of $150,000 for fire fighting under ordinary conditions, and supplements deficiency appropriations of over $900,000 incurred as a result of the disastrous fires of last summer.

The federal meat inspection, which has been enforced by the department from a permanent annual appropriation of $3,000,000, receives an indirect increase of $155,000 through the transfer of its clerical force to the statutory roll of the Bureau of Animal Industry. The Bureau of Chemistry receives $60,000 additional for the enforcement of the Food and Drugs Act, and the Weather Bureau $75,490 additional for its weather service. Provision is also made by an appropriation of $87,000 for the enforcement of the Insecticide Act, which became effective January 1, 1911, and for which a deficiency appropriation of $35,000 had been allowed for expenses to July 1.

A number of propositions involving general legislation were considered in connection with the bill, but as finally enacted the law remains substantially a routine measure. The secretary was again authorized to continue investigations on the cost of food supplies at the farm and to the consumer, and a special appropriation of $5,000 was added for a study of chestnut bark disease.

Comparison of the allotments to the various bureaus in this act and those preceding it is rendered difficult because their clerical employees will, in accordance with a clause inserted in the act of 1911, be transferred on July 1 from the various lump-fund appropriations on which a portion of them had been carried to the roll of positions specifically provided for. These transfers in certain cases—

as, for example, in this office and the Bureau of Statistics—involve but a few employees, but in the case of the Forest Service, where 1,894 forest rangers and similar employees are to be transferred, they occasion an apparent increase in the appropriations for statutory salaries from $60,200 for the current year to $2,318,680, with a corresponding deduction from lump-fund appropriations The lump-fund appropriations, therefore, for a particular purpose, such as biological investigations or soil-survey work, no longer indicate so completely as they did previously the entire expenditures for these objects Comparison is still possible, however, as regards the aggregate appropriations of the bureaus

The Weather Bureau receives a total of $1,600,250 Of this amount, $15,000 is for the restoration of the Weather Bureau station at Key West, Florida, wrecked by hurricanes in October, 1910 The allotment for maintenance of the bureau printing-office was reduced to $18,000 by reason of the recent transfer of a portion of the equipment to the Government Printing Office For investigation of climatology and evaporation $120,000 was provided, as at present

The appropriations to the Bureau of Animal Industry aggregate $1,654,750 Aside from the increase due to the transfers from the meat-inspection act, previously referred to, the chief additions are those of $7,120 for the tick-eradication work, making that appropriation $250,000, an increase of $7,000 for the work of the Dairy Division, making its total $150,000, and of $7,640 for the Animal Husbandry Division, or $47,480 for that work Under a new clause inserted in the act, the Secretary of Agriculture is authorized to permit, under certain conditions, the admission of tick-infested cattle from Mexico into those portions of Texas below the quarantine line.

New appropriations were made of $65,000 for the purchase of land for quarantine stations near Baltimore, Md, and Boston, Mass; $10,000 for equipping the 475-acre experiment farm which has recently been acquired at Beltsville, Md., and $16,500 for constructing buildings at this farm and that at Bethesda, Md It is expected to utilize the Beltsville farm for the experimental work of the Animal Husbandry and Dairy Divisions, and to reserve that at Bethesda for pathological investigations

One of the largest increases in the bill was accorded to the Bureau of Plant Industry, which will receive $303,480 additional, making its total $2,061,686 The lump-fund appropriation for general expenses is $1,441,586, which is divided among thirty projects Some of the largest of these are $350,000 for the boll-weevil campaign (a net increase of $106,945), methods of crop production in the semi-arid or dry-land sections, and for the utilization of lands reclaimed under the Reclamation Act, for which a net increase of $38,270 and a total of $143,060 is granted, $142,920 for the farm management studies, of which $4,000 is to be used in agricultural reconnoissance work in Alaska, studies of the production, handling, grading, and transportation of grains, for which $135,005 is available, an increase of $24,500, and the studies of fruit improvement and the methods of growing, packing and marketing fruits, which will have $87,735 The investigations of the cotton industry were extended to include the ginning and wrapping of cotton

For the purchase and distribution of valuable seeds and plants the allotment made was $289,680 This is an apparent decrease of $19,910, but it is accounted for in part by transfers of clerical employees to the statutory roll of the bureau, and in part by the segregation as a distinct project of $20,000, which was formerly supported from this fund The two items comprising this appropriation are the congressional seed distribution, which is continued on the usual basis, with $237,160, and the allotment for the introduction of seeds and plants from foreign countries, which is increased to $52,520

The appropriations to the Forest Service reached a total of $5,533,100, in addition to the various emergency appropriations to which reference has been made. This, as usual, represents the largest appropriation to any one bureau, and is also the largest increase

over the previous year, the total for 1911 having been $5,008,100 The policy of definite allotments to each of the 161 national forests for maintenance was continued The Nebraska National Forest was authorized to furnish young trees free of charge to settlers in the surrounding region

The sum of $150,000 was granted for fighting forest fires and for other unforeseen emergencies, of which $70,000 is immediately available The allotment for permanent improvements on the national forests was increased from $275,000 to $500,000 Provision was made for the refunding to claimants of moneys erroneously collected in the administration of the national forests, and for the granting of easements under certain conditions for rights of way across the public lands, national forests, and reservations, for the transmission of electrical power and for telephone and telegraph purposes

Liberal provision for the development of investigational work was also made, $177,040 being granted for investigations of methods for wood distillation and preservation and the economic use of forest products, including the testing of woods for paper-making, together with $18,420 for investigations of range conditions within National Forests and range improvement, $251,168 for silvicultural and dendrological experiments, and $33,760 for miscellaneous forest investigations and the preparation and dissemination of results

The appropriation of the Bureau of Soils was increased to $262,060 No appropriation was made for soil erosion investigations, for which $5,000 has been allotted annually for many years The soil survey work received $145,000, a net increase of $13,040, with a provision added limiting to 10 per cent the expenditures in any state

The bureau was authorized to undertake a new line of work by the appropriation of $12,500 "for exploration and investigation within the United States to determine a possible source of supply of potash, nitrates and other natural fertilizers," $2,500 being made immediately available It is expected that particular attention will be devoted to possible sources of potash in view of the present situation as regards the German potash supply. The work will also be supplemented by researches to be conducted by the Geological Survey, which received authority in the sundry civil appropriation act to expend $40,000 "for chemical and physical researches relating to the geology of the United States, including researches with a view of determining geological conditions favorable to the presence of potash salts" According to a recent announcement from the survey, the expenditure of half this appropriation for the potash exploration is contemplated

The Bureau of Entomology receives an aggregate of $601,920 This is an increase of $69,740, mainly for the extension of work to the alfalfa weevil and for enlarging the investigations on insects affecting rice and sugar-cane, for demonstration work against forest insects, and for additional studies in bee culture The largest single allotment is for the continuation of the campaign against the gipsy and brown-tail moths, for which the appropriation is $284,840

The large proportionate increase of $52,780 was accorded the Bureau of Biological Survey, making its total $139,700. All the various lines of work were continued on a more comprehensive basis, and new items were included of $2,500 for the purchase, capture, and transportation of game for national reservations, and of $20,000 for the feeding, protecting and removal of elk at Jackson's Hole, Wyo, and vicinity The latter appropriation is made immediately available and remains available until expended.

The activities of the Office of Public Roads have been rapidly increasing in recent years, and to keep pace with the growing demands the appropriation was increased from $114,240 to $160,720 A new line of work authorized is the conducting of field experiments in road construction and maintenance, for which $10,000 is granted

The total appropriation of the Office of Experiment Stations is $1,864,000, of which $1,440,000 is allotted to the state experiment stations under the Hatch and Adams Acts.

Of the remainder, $56,500 is for statutory salaries and $37,500, a net increase of $5,000, is for general expenses. The allotment of $10,000 for the agricultural education service was continued as at present.

The nutrition investigations received an increase of $5,000, making $15,000 available for this purpose. This increase will enable further extension of these investigations and the preparation of popular bulletins setting forth plans for the more economical and effective utilization of agricultural products as human food, for which data a strong demand has been in evidence.

An estimate of $20,000, submitted for the preparation, publication and dissemination of original technical reports of the scientific investigations of the experiment stations by the Secretary of Agriculture in cooperation with the Association of American Agricultural Colleges and Experiment Stations, was favorably recommended by both the house and senate committees, but failed of passage.

The Alaska, Hawaii and Porto Rico experiment stations were given $30,000 each, an increase of $2,000 in each case to equalize their funds with those received by the state stations from federal funds, and the Guam Station was continued at $15,000. The clause requiring the expenditure of $5,000 by the Porto Rico Station for coffee experiments was omitted, thereby restoring the coffee work to the same basis on which it has been conducted for many years previous to the passage of the act for 1911.

The irrigation and drainage investigations each received $100,000, a net increase of $32,820 and $25,980, respectively. These increases will enable the extension of these lines of work, especially in the rendering of assistance to settlers in newly irrigated regions, and in formulating plans for the reclamation of swamp lands. The provision requiring a special report of the aggregate expenses in the drainage investigations to date and the areas in the several states and territories which have been investigated was continued.

The work of the remaining bureaus was provided for along substantially the present lines. Including the increase previously noted for the enforcement of the Food and Drugs Act, the Bureau of Chemistry will receive $68,080 more than at present, and a total of $963,780. The Bureau of Statistics is given $231,020, the Library, $40,500, the Office of the Secretary, $276,450, the Division of Accounts, $97,520, the Division of Publications, $209,960, and the fund for contingent expenses, $110,000. These all contain small increases, occasioned in general by the growth of the department.

In addition to the sums carried in the appropriation act itself, there should also be considered the appropriation of $470,000 for the department printing and binding, which appears in the appropriation act for sundry civil expenses. This represents a nominal increase of $10,000, but $22,000 more than at present is assigned to the Weather Bureau by reason of the transfer of a portion of its branch printing office, making a virtual decrease of $12,000 for the remainder of the department. There is also to be added the permanent appropriation of $3,000,000 for the meat-inspection work. Deficiency appropriations were granted, as well, of $923,192.90 for the fighting of forest fires in 1910, the relief of employees of the department killed or injured in that campaign, and for horses and equipment destroyed during it, and $35,000 for the enforcement of the Insecticide Act during 1911.

Additional funds which will be administered by the department are provided in the measure enacted at the recent session of congress for the protection of the watersheds of navigable streams, and popularly known as the "Appalachian Forest Reserve" Act. Under this act the secretary of agriculture may expend $200,000, in cooperation with states requesting it, in the protection from fire of the forested watersheds of navigable streams, irrespective of ownership. He is further authorized to purchase, following a favorable report by the Geological Survey and the approval of a National Forest Reservation Commission, of which he is *ex-officio* a member, lands located at the headwaters of navigable streams,

and to administer these lands as permanent national forests An appropriation of $2,000,000 is made annually until July 1, 1915, for the examination and acquisition of these lands, together with $25,000 additional annually for the expenses of the commission

Eliminating the deficiency appropriations and that for the Forest Reservation Commission, these various appropriations, which are intimately connected with the work of the department, would, if added to the regular appropriations, make a grand total of $22,570,016 This is a large sum, but as was pointed out by Chairman Scott in concluding the presentation of the bill, "the money appropriated for the Department of Agriculture is an investment and not an expense And that it has been a good investment the statistics showing the expansion of agriculture and the improvement in methods throughout our country bear eloquent witness During these past ten years, while the Department of Agriculture has been expending $90,000,000, the farmers of the United States have added to the wealth of the world the stupendous and incomprehensible sum of $80,000,000,000 Without anything like a corresponding increase in the area of land under cultivation, the value of the farm products of our country has risen from slightly more than $4,000,000,000 ten years ago to nearly $9,000,000,000 in 1910

"The conclusion is inevitable, therefore—and that conclusion could be made incontestable by innumerable other proofs if time permitted—that the farmers of America are applying better methods and getting better results from their labors than ever before And in devising these better methods, in pointing the way for better results, the Department of Agriculture has been the undisputed leader, as it should be, and has thus beyond cavil or question derived from the money it has expended a percentage of profit to all the people which can not be calculated"

APPROPRIATIONS FROM THE BACHE FUND OF THE NATIONAL ACADEMY OF SCIENCES

DURING the past year the following grants have been made from the Bache Fund of the National Academy of Sciences

May 20, 1910 Franz Boas $300
Investigation of head forms of new born children

May 20, 1910 John A Parkhurst 500
Photometric and spectroscopic survey of circum polar stars

June, 1910 Louis T More 500
Continuation of investigation on discharge of electricity through gases, radioactivity and electro magnetic action (second appropriation, first made in May, 1908)

December 9, 1910 S F Acree 400
Investigation of reactions of alkyl halides with sodium ethylate

January 25, 1911 P W Bridgman 500
Effects of high pressure, variation of freezing point of liquids with pressure, compressibility of liquids and solids, and mechanical properties of metals

February 2, 1911 Francis B Sumner 250
Experiments on effects of external conditions on growing white mice

April 17, 1911 E W Washburn 200
To prepare and measure the specific conductance of pure water

April 17, 1911 Gilbert N Lewis 500
The determination of the electrode potentials of the alkali metals and of the metals of the alkaline earths

April 17, 1911 Charles C Adams 125
For the expense of completing and preparing for publication a paper entitled "The Geographic Variations and Relations of CO"

SCIENTIFIC NOTES AND NEWS

COLUMBIA UNIVERSITY has conferred its doctorate of laws on Professor C. F. Chandler, who retires this year from the chair of chemistry after forty-seven years of active service.

SIR WILLIAM T THISELTON-DYER, formerly director of the Kew Botanic Gardens, will receive the honorary doctorate of science from Oxford University on June 28

DR C S SARGENT, director of the Arnold Arboretum, Harvard University, has been elected an honorary member of the Société Nationale d'Acclimation de France, and an honorary member of the Royal Irish Academy

Dr Joseph H White, of the U S Public Health and Marine Hospital Service, was elected president of the American Society of Tropical Medicine at its recent New Orleans meeting

The trustees of the Jefferson Medical College, Philadelphia, on the recommendation of the faculty, have elected Dr Warren B Davis as the Corinna Borden Keen research fellow of the college This election carries with it an award of $1,000 for the purpose of a year's research work in Europe upon any subject approved by the faculty

A grant of two hundred dollars has been made from the C M Warren Fund of the American Academy of Arts and Sciences to Dr S F Acree, Johns Hopkins University, for the study of the physical and chemical properties of pure ethyl alcohol A grant, amounting in all to one hundred and fifty dollars, has also been made to Dr J E Gilpin, Johns Hopkins University, in aid of his work on the study of the nature and source of petroleum, which involves results on the fractionation of petroleum by means of selective absorption by porous materials, such as fuller's earth

Curator Bashford Dean, of the department of ichthyology and herpetology in the American Museum of Natural History, has been appointed the official representative of the museum at the twenty-second annual conference of the Museums Association, which will be held in Brighton, England, from July 10 to July 15, under the presidency of Mr H M Platnauer, B Sc, and at the one hundredth anniversary of the founding of the Universitas Regia Fredericiana at Christiania, which is to take place on September 5 and 6.

Professor Albert Johannsen, of the department of geology of the University of Chicago, will sail from Montreal on the seventeenth of this month to inspect the petrological laboratories of the principal European Universities.

Dr. C. H. Shattuck, head of the department of forestry at the University of Idaho, will during the coming summer conduct a forestal and floral survey of the Kaniksu National Forest This survey will be similar to that conducted by him last summer on the Clearwater National Forest The party will consist of twelve men with headquarters at Coolin, Idaho

Sir John Murray lectured before the California chapter of Sigma Xi on May 11 on "The Floor of the Ocean," using illustrations from the recent cruise of the Norwegian steamer *Michael Sars* in the Atlantic

The annual public address before the University of Michigan chapter of the society of the Sigma Xi, was delivered, June 2, by Professor J Playfair McMurrich, of the University of Toronto, the subject of the address being "Sir Francis Galton, his Life and Work" Professor F G Novy was elected president of the chapter

An address on "The Evolution of Human Teeth and their Racial Differences," was delivered by Dr A Hrdlicka, of the Smithsonian Institution, on June 1, at Toronto, under the auspices of the Ontario Dental Society, and on June 27 before the Alumni of the dental department of the University of Buffalo On May 25 a similar address was given by Dr Hrdlicka before the Maryland State Dental Association, at Baltimore

Mr A D Darbishire has been appointed to the newly instituted lectureship in genetics, at the University of Edinburgh, and will deliver a course of six lectures on heredity during the summer session

The statue to Captain Cook, the plans for which have been noted in Science, will be placed on the Mall side of the Admiralty arch, on the right hand going towards Charing Cross The execution of the statue has been entrusted to Sir Thomas Brock

The executive committee on the Chiene portrait fund has resolved to hand to the University of Edinburgh the balance of the fund, about $1,500, for the foundation of a bronze medal, to be called the "Chiene Medal in Surgery."

Dr. Edward Burnett Voorhees, professor of agriculture at Rutgers College and direc-

tor of the N J Agricultural Experiment Station, known for his important contributions to agricultural chemistry and agricultural education, died on June 6, aged fifty-four years

PROFESSOR WILLIAM RUSSELL DUDLEY, since 1893 professor of botany in Stanford University, died on June 4, aged sixty-two years

MRS. EMMA WILSON DAVIDSON MOOERS, custodian of the neuropathic collection of the Harvard Medical School, previously assistant pathologist in the Worcester and Maclean Hospitals, died on May 31

THE death is announced of Mr Robert Service, of Dumfries, Scotland, who while conducting the work of a nursery made valuable contributions to ornithology

THERE is existing a vacancy in the position of physical chemist in the Bureau of Mines, Department of the Interior, at Washington, D C This position requires a high order of scientific training equivalent to that required by the leading American universities for a professorship in physical chemistry A man is wanted who will be able to organize, to participate in, and to supervise the physical and chemical investigations of problems that serve as a basis for modern metallurgical methods, especially the problems connected with the ores, operations and products of modern smelters The government is endeavoring to find the best man available for this work and has no particular individual in view The methods of procedure will be similar to those of an educational institution or business organization, whose board of trustees or governing officers desire to fill professional or technical positions The qualifications and fitness will be determined by an impartial board of scientific men The entrance salary for this position is $4,000 per annum There is also existing a vacancy in the Bureau of Mines in the position of chief mechanical engineer, at an entrance salary of $4,800 per annum For this position it is desired to secure a man who will be able to participate in and supervise the various mechanical engineering problems appropriate to the work of the Bureau of Mines, including investigations looking to a greater efficiency in the utilization of mineral fuels at the various heating and power plants of the government in different parts of the country, and the mechanical problems connected with various mining operations Qualified persons who are interested in these positions are invited to communicate with the U S Civil Service Commission, Washington, D C, at an early date, since the selections will be made about the middle of July

ACCORDING to a bulletin issued by the Bureau of Statistics the month of May was not, on the whole, very favorable for crop growth, drouthy conditions having prevailed over a great portion of the United States In consequence the average condition of crop growth in the United States on June 1 was 2 8 per cent below the average condition on that date Some relief from the unfavorable conditions came at the close of May and first part of June A comparison of the conditions of various crops on June 1, with their average growing condition on June 1 of recent years (past ten years for most crops) is shown as follows (100 representing average conditions and not normal) cotton 108 5, sugar beets 103 2, apples 102.5, raspberries 101 8, spring wheat 101 1, watermelons 100 6, pears 99 7, cantaloupes 99 6, blackberries 99 5, sugar cane 99 5, barley 99 2, winter wheat 98 5, rye 98 2, oats 96 9, alfalfa 96 1, onions 95 5, lima beans 92 5, cabbage 91 0, pastures 90 2, hemp 89 0, clover hay 84 6, all hay 85 1, peaches 83 5 The above figures relate only to relative growing conditions, not taking into account changes in acreages Taking into account both acreage and condition, indications are for about 9 9 per cent larger wheat crop than was produced last year, and 10 2 per cent larger than the average of the past five years, oats crop 13 3 per cent less than last year, but 4 8 per cent more than the average of the past five years, barley 8 per cent more than last year, and 5 3 per cent more than the five-year average Total areas have not been estimated for the other crops, except that the rye area planted is about 1.2 per cent. less

than last year Clover (for hay) acreage 6 3 per cent less and sugar cane acreage 0 4 per cent more than last year

UNIVERSITY AND EDUCATIONAL NEWS

The Harvard Medical School has been bequeathed $22,000 by the will of the late Professor Samuel Hubbard Scudder, the eminent entomologist

Governor Dix has signed a bill that appropriates $235,000 for the state colleges of Cornell University The Veterinary College receives $140,000 for a new building and $50,000 is appropriated for a heating plant This bill is independent of the annual bill for maintenance, which has not yet been passed

At the Bryn Mawr College commencement announcement was made of a bequest of $150,000 from Phoebe Anna Thorne, of New York, who died in 1909, to endow an associate professorship of education and the Phoebe Anna Thorne Model School to be conducted by the college as an experimental high school in connection with a graduate school of education.

Columbia University has received a gift of $10,000 annually for five years from Mr Charles H Davis, C E ('87), for the support of advanced instruction in highway engineering and Professor Arthur H Blanchard, of Brown University, has been appointed professor of highway engineering. Among other gifts announced are $45,000 from the committee appointed to raise the Richard Watson Gilder Memorial Fund to establish the Gilder fellowships in good citizenship, $33,133 from the committee appointed to raise the William T Bull Memorial Fund, to establish a fund for research in surgery, and $20,000 from an anonymous donor for the equipment of the research laboratories in electro-mechanics

Dr Eugene A Noble, president of Goucher College, has been elected president of Dickinson College

Miss Ellen Fitz Pendleton, dean, acting-president and associate professor of mathematics of Wellesley College, has been elected president of the institution.

Dr Michael I. Pupin, professor of electromechanics in Columbia University, has been designated to serve as director of the Phœnix Research Laboratories In this capacity, Professor Pupin will be in general charge of the development of the research work in the department of physics

In the School of Education of the University of Pittsburgh the following appointments have been made Henry Davidson Sheldon dean of the School of Education in the University of Oregon, has been made professor of the history of education Dr Sheldon will spend next year in Europe on leave of absence and will take up his work in Pittsburgh in the fall of 1912 Charles Barr Robertson, director of the schools of practise and professor of psychology and education in the Cortland, N Y, State Normal School, has been called to the professorship of secondary education, and will organize and direct the practise teaching and the cooperative relations of the high schools and the university

The Johnston scholarships, of the Johns Hopkins University, "offered primarily to young men who have given evidence of the power of independent research," have been awarded by Johns Hopkins for 1911–12 to James Ryals Conner, Ph D, in mathematics, Franklin Edgerton, Ph D, in Sanskrit, and Joseph T Singewald, Jr, Ph D, in geology The Adam T Bruce fellowships, bestowed upon candidates who are considered "most likely to promote biological science, and especially animal morphology, by original research," have been awarded to Elmer J Lund, Ph B, in botany, and David H Tennent, Ph D, in zoology

Dr Frederick P Lord, of Iowa City, formerly connected with the department of anatomy of the State University of Iowa, has been appointed as the head of the department of anatomy of Dartmouth Medical School

Dr J F Shepard has been promoted from instructor to assistant professor of psychology at the University of Michigan.

A new chair of machine design has been created in the engineering department of the University of Michigan, to which Professor Woldenburg, of Charlottenburg, Germany, has been appointed.

MR ROBERT NEWSTEAD, lecturer in economic entomology and parasitology in the Liverpool School of Tropical Medicine, has been appointed to the newly-established Dutton Memorial chair of entomology in the University of Liverpool

DISCUSSION AND CORRESPONDENCE

VITALISM AND EXPERIMENTAL INVESTIGATION

IN connection with the recent helpful discussions of vitalism by Ritter[1] and Lovejoy,[2] one point seems worthy of further emphasis Some men are interested in science because of its bearing on general philosophical problems, others are interested in philosophical problems because of their bearing on the way to go to work in science Both attitudes are proper enough, but one's treatment of such a question as vitalism is largely determined by which of these attitudes he takes The point I wish to emphasize arises from the second attitude Has vitalism (in any of the brands set forth by Lovejoy) any bearing on the theory and practise of scientific investigation?

This is a practical question in which the experimentalist as such must be interested, even though he may pride himself on his indifference to philosophical speculation One kind of vitalism appears to me to affect fundamentally the theory of scientific work, for this reason this kind appears of more interest than the other, if not the only kind worth distinguishing

The man of science at work with his two hands is trying to find the determining conditions for what takes place in matter and energy, and how these conditions act In so doing he is led to make a study of the various possible methods of work, and particularly of the various ideas and devices that are presented to him as deserving consideration in his work Many such things come to the worker in biology from outside his own special field; particularly from physics and chemistry Such were the theories of electric dissociation; much in the physics of colloids, and the like. The biologist is compelled to examine these to see how useful they are in his own experimental analysis, often he finds them of the greatest value and he modifies his methods of work accordingly

Various theories of vitalism have likewise been brought to the attention of the investigator, but as a rule he has taken little interest in these, because they seemed of such a nature as not to affect his work, they seemed merely general suggestions and reflections on the fundamental meaning of what one sees in biology, of interest primarily to the man for whom science is the handmaid of philosophy, rather than the reverse They did not attempt to provide an instrument for actual use in experimentation, nor an idea according to which scientific practise must be altered

This appears to be the case with the first kind of vitalism distinguished by Lovejoy, a vitalism which holds that there are new modes of action in living things, but that the new modes of action are nevertheless functions of the configuration of the matter and energy involved, so that after we have discovered how a given physical configuration acts, we can depend upon it, as we depend upon such constancy in the inorganic sciences Such a vitalism involves no fundamental change in our methods of work, we continue to test, by fitting methods, how given configurations act, and to record the results in proper generalizations, exactly as in physics and chemistry Biology would then, so far as scientific method is concerned, bear the same relation to physics and chemistry that any unexplored part of these sciences bears to the explored parts. The distinction between vitalistic science and physical science would have but a very mild interest for the worker with his hands; it has no pragmatic bearings

On the other hand, the second kind of vitalism distinguished by Lovejoy makes assertions which would if true require serious consideration in actual practise, indeed, it is put forward by its advocates as supplying certain factors which require consideration on the same grounds as do electric dissociation and osmotic pressure; factors without which our experimental analysis is bound to be incomplete or wrong. Its acceptance would logically

[1] SCIENCE, March 24, 1911

[2] SCIENCE, April 21, 1911

produce fundamental changes in the principles of experimentation This is the point which, to me as an experimenter, seems hardly to receive adequate consideration by Professor Lovejoy; this appears to me the reason why this particular kind of vitalism (the vitalism of Driesch) has received so much attention from investigators, though as a rule they are rather indifferent to vitalistic theory This is the vitalism which holds that the laws of what occurs in organisms "can not even be stated in terms of the number and arrangement of the organism's physical components."[3] This statement means, if it means anything, that you can not make a statement *which will hold*, that a given arrangement of physical components will act in a certain definite way (even after you have observed how it acts) If such a statement will not hold, this can be only because the same arrangement of physical components acts sometimes in one way, sometimes in another—so that there results indeterminism so far as the physical components are concerned[4] If vitalism of this sort is correct, then the biologist can not from a knowledge of the total physical configuration predict what will happen, even after he has observed it

To realize the situation in which this leaves the experimenter, it is needful to consider just what his work consists in The experimental investigator is engaged in discovering the determining causes of things Just what we are to understand by *cause* has given rise to much discussion, often leading far away from any experimental concept[5] Experimentally it means any preceding event or condition without which the event we are studying would not have occurred Now it turns out in experimentation that everything has a very great number of such "causes," all standing on the same experimental footing, so that to determine "the cause" of any event, taken by itself, is a hopeless task, so taken, the meaning of *cause* becomes undefinable, unless it could be held to signify finding out everything that must have happened in order that this event may occur Progress can be made only when we so state our problem that we need search for but one determining cause at a time Now, *one single sufficient experimental cause can be found only for the difference between two cases,* and the actual practise of experimental investigation consists in comparing two cases and finding experimentally what determines the difference between them, discovering, that is, what preceding difference results experimentally in producing the present difference

An example will make this clear An organism is observed to move over a certain stretch, from *a* to *b* What is the cause of this? The question so put opens up a vast perspective, we may go into the production of the energy which brings about the movement, with the infinite number of questions that this involves, we may study the special organs by which this organism performs its movements, and how these organs were produced, we may take up the stimuli which set the organism in motion, and those which determine its direction, the environmental conditions on which the motion depends, etc All biological science is before us, where shall we take hold? We must make our question precise, and this can be done by considering two differing cases This specimen now swims in a certain direction, this other (or this same one at a different time) in a different direction What is the cause *of this difference?* A little experimentation shows that the one, only and sufficient cause is the different direction of the rays of light in the two cases Or, again, this specimen swims in a certain direction, while

[3] Lovejoy, *l c*

[4] A natural result of this is to do what Driesch does and what Lovejoy seems inclined to deprecate, to assume the existence of some non-physical factor, as entelechy, to supply the missing differential determining condition This grows out of the ordinary procedure in experimental investigation; whether it really helps the experimenter in his work we shall inquire in a moment

[5] The ambiguities in the word cause have induced some investigators to drop it entirely, and deal only with words having no implication that is not definable in experimental terms, so Verworn in the fifth edition of his "General Physiology"

this other does not, even though the direction of the rays of light is the same What is the cause of *this* difference? Experiment shows it to be the different temperature in the two cases In another case the difference in motion is found to be due to difference in chemical conditions, or to difference in the amount of food taken, or the like Many times we find that there are two or more different factors, any one of which will produce the difference in question, or that the observed difference will not result unless two or more determining factors are combined These are only details of application, the method throughout is to take two cases differing in a certain respect, then to find the (experimental) determining cause for this difference By continuing this process, comparing all possible degrees of difference, the causal analysis may be carried to any desired degree of minuteness —till the smallest perceivable differences are reached The process may be continued backward, tracing step by step how the determining differentials for any given case are themselves determined, until we have as full an experimental analysis as we desire, there being no end to the process of analysis, save as practical considerations compel us to stop[6]

The investigator may of course not always actually have the two cases present before him, he may not even think of the concrete existence of more than one of the cases, but the rationale of the process, when analyzed, is that which we have set forth[7]

Now, the fundamental principle on which this work of the investigator is based is this *When two cases differ in any respect, there will always be found a preceding difference to which the present difference is* (experimentally) *due* This principle is, explicitly or implicitly, constantly present with the experimenter If two experiments, supposedly alike, give different results, *there must be some preceding difference to account for this* The investigator is so convinced of this that it does not occur to him to doubt it or state it or consciously raise the question at all, he merely sets to work to find what the difference is, and he may spend hours or days or years in his search This principle is the air the experimenter breathes, the water he drinks and the food he takes It is what makes him an experimenter If he should become convinced that it does not hold, the logical thing for him to do is to follow the finely consistent example of the sponsor for the kind of vitalism that asserts that it does not, and drop experimentation to take up philosophy

The question whether this principle is correct need not concern us now, what I wish to bring out is the tremendous difference in scientific investigation in two fields, in one of which this principle holds (as it is supposed to do in physics and chemistry), while in the other it does not (as in biology, according to this sort of vitalism) The investigator in the field where it does not hold would be continually in doubt as to what to do Here are two experiments that result differently But is it worth while to search for an experimental determining factor for this difference? Perhaps there is no such factor—for this is biology, not physics The guiding principles are different in the two fields; while we might in physics be certain that an experimental cause could be found for the difference, in biology we can not, for in biology the same configuration may give sometimes one result, sometimes another This is a difference in principle that would really make it worth while to separate the two sets of sciences in a fundamental way; this would give us a vitalism that had some practical consequences.

But what should be the further procedure of the biologist in view of the fact that two complexes absolutely identical in their phys-

[6] The farther work, of comparing the results of this analysis and recording them in fitting generalizations, by which the heap *of facts is* reduced to an ordered whole, does not concern us here

[7] Thus, when the investigator merely asks What determines the *direction* of this movement—the experimental question essentially is, When this specimen moves in a certain direction, while another does not, what determines the difference between the two cases? Neglect to analyze problems into this form leads to much of the inconclusive work and difference of opinion in experimental biology.

ical[9] make-up give different physical results? Shall he abandon the principle of "univocal determination," not merely from a practical experimental standpoint, but completely? Or shall he follow Driesch's example and try to save the principle by assuming that the two cases differ in something non-physical (which he may call entelechy if he likes the word)? Professor Lovejoy's suggestion that this latter is a hypostasis hardly warranted in strictly scientific procedure, would leave us absolutely without determining cause for the difference, the experimenter could but admit the failure of the principle on which his work is based, lay down his arms, and surrender But does Driesch's assumption of a non-physical differentiation between the two cases leave the experimenter in a better situation?

Driesch's statement to save the principle of determinism in such a case is as follows. "given certain circumstances, and given a certain entelechy in a certain state of manifestation, there will always be or go on one specifically determined event and no other"[9] Thus under the conditions we have sketched, the investigator could comfort himself (if he found it a comfort) with the assertion that different entelechies were at work in the two cases, or that the same entelechy was at work in different manifestations (the latter formula would be forced upon us by the vitalistic arguments from behavior) Now, what is the difference between attributing experimental results to such non-physical determiners, and the ordinary experimental procedure of attributing them to physical determiners?

The difference lies in two points (which are perhaps fundamentally one) (1) Any physical factor has various manifestations, the conditions for each of which are discoverable and constant, it is bound up in many different ways with the rest of the conditions Hence if the experimenter attributes a result to a certain physical factor, this is at once open to test, we may try whether its other manifestations appear as they should if it is in presence, it leads at once to farther experimentation, and the explanation must stand or fall in accordance with the results of this experimentation On the other hand, the non-physical entelechy may give different manifestations (or none at all) under the same conditions, there is no way that we can test the affirmation that a given experimental result is due to it A physical factor that showed itself in one unique manifestation, and might later show itself under the same conditions in a different manifestation would of course leave the experimenter as helpless as does entelechy, but such a "physical factor" is a contradiction in terms, it is because entelechy has this character that it is a non-physical factor[10] Thus attribution of a result to entelechy closes the door to farther experimental test

2 In experimenting in non-vitalistic fields, after we have discovered what preceding differences determine (experimentally) our given diversities, we may move a step back and discover in the same way what determined those preceding differences, and this process of carrying back the experimental analysis is without end (save from practical difficulties) On the other hand, as soon as the experimenter has attributed his observed diversities of result to different manifestations of entelechy he is at the end of his experimental rope What determines, under the same physical conditions, the different manifestations of entelechy? The problem is not only practically, but by hypothesis, beyond the reach of experimentation[11]

[8] I am throughout using the word *physical* in place of "physical and chemical," "physical or chemical" and "physico chemical"

[9] "The Science and Philosophy of the Organism," II, 153–154.

[10] If, as some have suggested, entelechy is to be considered merely a name for a factor whose dependence on the rest of the conditions and whose uniformity of action is not yet known, we should of course by this assumption drop our vitalistic theory; it is by vitalistic hypothesis that entelechy has the peculiarities mentioned above

[11] "Organic systems are governed by entelechy, and therefore contain all possible future perceptible diversities in an *imperceptible* form," Driesch, "Science and Philosophy of the Organism," II., 198.

Thus the bringing in of entelechy as a determiner is at most a pad to soften the experimenter's fall, a way of distracting his attention for a moment from the dolorous fact that his method of work has failed It merely puts off for one single step the admission that the principle on which experimental investigation is based breaks down when applied to biology Physical science and vitalistic science are then distinguished by a fundamental difference in the principles of investigation, of the highest practical consequence

Some attempts are made to console the biological experimenter for this difficulty, to make light of the difference in investigation in the two fields Professor Lovejoy comforts us by saying that in the case of the developmental processes on which Driesch partly bases his argument you could "if you go back to an early enough stage in the given sequence of processes" find "perfectly definite, perceptible and experimentally ascertainable constant antecedents" for the observed procedure, this in view of the fact that men do not gather figs of thistles, nor whales of sea urchin's eggs, to get a given type of adult you must at least have the egg of that type Thus only that immense field of developmental processes which lies between the egg and the adult would be exempted from experimental determinism! This might yield some solace to those whose life work does not lie in this field, were it not that Lovejoy quite leaves out of account Driesch's arguments and conclusions for the other fields of animal activities, particularly for behavior In behavior, according to Driesch's vitalism, what the animal does depends as much on the non-physical entelechy as it does in development, and yet there is no single type toward which each act tends.[12]

Again, some have assured the writer that we may accept this kind of vitalism and still go ahead with our work just as if experimental determinism still held, that in fact cases where it doesn't hold probably occur only under rare and recondite conditions, which we may never meet This vitalism, reserved like the religion of some individuals for Sunday consumption only, receives no encouragement from any close examination of vitalistic theory Taking as an example Driesch's working out, we find that we may expect the vitalistic factor to show its action continually in all sorts of work with living things According to Driesch the precise work of the vitalistic factor is to "suspend for as long a period as it wants any one of all the reactions that are possible with such compounds as are present, and which would happen without entelechy And entelechy may regulate this suspending of reactions now in one direction and now in the other, suspending and permitting possible becoming whenever required for its purpose This faculty of a temporary suspension of inorganic becoming is to be regarded as the essential ontological characteristic of entelechy"[13] That is, when there are in juxtaposition a number of substances which, according to purely chemical laws, would interact, giving certain results, entelechy may (or may not) interfere, preventing the union of certain of these, until the resulting products are determined by those that have been allowed to interact Thus from the same mixture of chemicals we shall get sometimes one product, sometimes another (depending on the purposes of entelechy); the variety of results thus obtainable from a given complex is of course very great. Now, all living things are complexes of great numbers of

[12] Thus Professor Lovejoy can not be followed when he states that "All that Driesch maintains is that such a [morphogenetic] process once started continues toward its normal consummation even if, after the start, some of the usual machinery instrumental to the consummation is lost and the rest has to redistribute and redifferentiate itself in order to keep things moving in the customary manner." This is only one of the observed facts on which Driesch bases his vitalistic theory, he has published an entire book on vitalism in behavior, and a large proportion of "The Science and Philosophy of the Organism" is devoted to the same subject One gets a very inadequate idea of the real nature of his theory by supposing it limited to morphogenesis, his conclusions reach far beyond this

[13] "The Science and Philosophy of the Organism," II, 180

chemicals, so that the condition under which entelechy comes into play is always realized. We may therefore expect its action at any step in our work; we must be prepared at all times to find the same physical configuration giving rise now to one result, now to another; we can have no confidence that when two experiments give different results, it will be possible to find an experimental cause for this difference.

Doubtless there are investigators who can persuade themselves that they really believe this sort of thing, and yet who can continue hopefully their hopeless task of trying to discover experimentally the conditions that determine what happens—just as there are persons who assert that they believe certain orthodox religious doctrines and yet live cheerfully the life of the worldly. But for one who takes his experimental work seriously and who has use for theories only as *theories of practise*, the acceptance of such a doctrine can not fail to profoundly change his work and his attitude toward his work.[14] It takes away the guiding principle on which every step of his work is based.

Thus a doctrine which holds to consistent physical determinism in the inorganic sciences and rejects it for biology makes a tremendous difference in principle between the two fields, a difference big with practical results. I believe that to most working investigators of biology the question of vitalism means the question whether there is such a difference, and it appears unfortunate that this question should be obscured by confusing it with the (for the working investigator) relatively inconsequential question as to whether anything happens in living things that doesn't happen in those not alive.

H. S. JENNINGS

JOHNS HOPKINS UNIVERSITY,
May 16, 1911

[14] Of course there would still be work for the biologist. Descriptive and observational work would be little affected. The biologist could substitute "entelechy" for "god" or "providence" or "nature" in the pious expositions of the naturalists of two generations ago, and devote himself to showing the wonderful and unfathomable ways of entelechy. If of an incurably analytic turn of mind he could even examine the limitations which the physical conditions place upon entelechy, and perhaps make a catalogue and classification of the various results produced by entelechy from a given physical configuration. It is the principles, methods and objects of experimentation that would be changed.

THE APPLICATION OF THE METHOD OF LEAST SQUARES

TO THE EDITOR OF SCIENCE: It would, I think, be interesting and valuable to have a consensus of opinion from both astronomers and physicists as to the limits within which the application of the method of least squares is permissible. This method is used widely by astronomers and but rarely by physicists. Moreover, I believe most physicists would hesitate to push the application of the method as far as is commonly done by astronomers.

To take a concrete case. During the discussion that followed the Saturday afternoon symposium at the recent general meeting of the American Philosophical Society, one point under discussion was whether or not the principle of relativity requires the abandonment of the concept of the ether. The writer mentioned as an *experimentum crucis* the possibility of detecting an ether-wind by measuring the speed of light in a single direction and over a path which for its greater part lay remote from the surface of the earth, thus avoiding a limitation of the Michelson-Morley experiment. It was suggested that if the measurement of the speed of light by Romer's method could be carried out with sufficient accuracy, and at two such times that the light would have to travel with and against the proper motion of the solar system, such an ether-wind might be observed. It was pointed out that the difference of time to be expected would be of the order of one fifteenth of a second. Some doubt was expressed as to whether this accuracy was yet attainable in a difficult measurement of this nature.

To this Professor Pickering replied that a large mass of such data was already in the possession of the Harvard Observatory, and had been discussed and reduced with this very

point in mind, and with a negative result In response to a query from Professor Doolittle as to the precision of the observations Professor Pickering stated from recollection that the error of a single observation might be three or four seconds, but that the hundreds of observations available brought the probable error well within the precision required

It seems to me there is room for an honest difference of opinion as to the value of the method of least squares in a case like this, where the error of a single observation may be forty-five or more times as great as the quantity to be detected Surely we must draw a line somewhere

While I have given this point no extended investigation, I may formulate my own opinion, as a basis for discussion, in the form of a mathematical theorem

The value of the measure of precision obtained by applying the method of least squares varies inversely as the ratio e/q (where $e =$ error of a single observation and $q =$ quantity to be measured), in such a manner that when $e/q = 1$ the value is zero, and for $e/q > 1$ the value is wholly imaginary

PAUL R HEYL

DR BRUSH'S THEORY OF GRAVITATION

TO THE EDITOR OF SCIENCE The article by Dr Brush on "A Kinetic Theory of Gravitation" in SCIENCE of March 10, will become of great interest to physicists when the author does what he partly promises to do in a future paper, viz, explains how a body which is perfectly transparent to a given radiation can shield another body from that radiation, and why, if the other body is also perfectly transparent, it makes any difference whether it is shielded from the radiation or not It would appear to be immaterial, so far as the effect upon the body is concerned, whether the atoms of a body through which this radiation is streaming in all directions are "buffeted about in every direction by the ether waves in which they are entangled" or whether they remain undisturbed by these waves, so long as they do not absorb any energy from the radiation

Dr Brush says that in the former case, "Each atom or molecule may be regarded as a center of activity due to its kinetic energy of translation, with continual absorption and restitution of the ether's energy normally equal in amount" This seems to the present writer equivalent to saying that a perfectly transparent body may be regarded as one in which the atoms are continually absorbing and radiating equal quantities of the same kind of energy If anything can be gained by making such an assumption, there seems to be no objection to making it, and I, for one, shall look forward with interest to Dr Brush's explanation of how it will enable such a transparent body to cast a shadow

FERNANDO SANFORD

STANFORD UNIVERSITY

SCIENTIFIC BOOKS

Soil Fertility and Permanent Agriculture By CYRIL G HOPKINS, University of Illinois Pp xxiii + 653, 14 illustrations, 3 colored maps Boston, New York and London, Ginn & Co Price $2 50

Of this work the author says "The chief purpose of this volume is to bring together in convenient form the world's most essential facts, gathered from the field and laboratory, and to develop from them some foundation principles of permanent agriculture" The book is a notable contribution to the foundations of practical agriculture, treated in an introduction and four parts, I, Science and Soil, II, Systems of Permanent Agriculture, III, Soil Investigations by Culture Experiments, IV, Various Fertility Factors

The method of treatment adopted is admirable but not that usually chosen by writers on either soil or agricultural chemistry The book takes a distinct place in agricultural literature and will be found a mine of information and valuable reference to the subjects it treats Professor Hopkins holds persistently throughout the volume to the thesis named in the title and does not aim to treat in detail a wide range of topics, but has built his treatment upon a broad, most substantial

foundation of germane data, thoroughly and logically cemented The 121 tables of foundation data are mostly the results of well conceived, long continued, carefully measured and verified experiments, executed both in Europe and in this country They are not only put into effectively illuminating form by the author and discussed, for his purpose, with good discrimination, but they will be found most valuable references for many other purposes

Some will question the wisdom of recalculating the data of some of these tables on the basis of the elements but there can be no doubt that this method serves much better for comparative study, and had earlier investigators adopted the plan no serious criticism would be urged We feel that the author should have gone a step farther and expressed all results on the basis of weight and of dry weight, wherever possible The amounts of plant food elements and of water removed from the soil by a bushel of potatoes, oats and wheat have no proper comparative relation, as they do when expressed on the basis of dry substance

Within the last few years there has been such a pronounced growth of public appreciation regarding the importance of the maintenance of soil productivity that plant physiologists, pathologists and geologists, with others, are following the lead of bacteriologists in efforts to see if in their fields there may not exist relations which will enable their observations to shed important light on the complex problems involved This is progress along hopeful lines and such investigators may feel that the volume before us does not give sufficient prominence to these newer lines of research But as Professor Hopkins has written for the educated farmer, and from the standpoint of every-day field practise, he has wisely chosen not to obscure that which has been proven by prolonged careful research, checked by practical experience, with the presentation of theories suggesting practises not yet tried, which may or may not prove helpful.

Ten chapters are devoted to science and soil, in which fundamental facts and principles are stated, followed by presentations regarding plant food elements and compounds, plant food and the earth's crust as an original source, and soil formations and classifications, two maps being given, one for Illinois and the other for the United States The composition of soils in general is treated, followed by that of soils of eastern, central, northern, southern and western United States, expressing the results in amounts contained in two million pounds of dry surface soil, or approximately that contained in an acre to the usual depth of plowing Ten residual soils of Maryland are shown to carry 720 to 1,500 pounds of phosphorus, while the Illinois soils range between 810 and 2,030 pounds per two million pounds of dry soil These amounts Professor Hopkins considers would be removed by approximate maximum crops in a rotation of wheat, corn, oats and clover in from 37 to 105 years, or if only the grain is sold, in from 68 to 192 years

It is highly probable that no normal soil can experience the withdrawal of any considerable proportion of its phosphorus without suffering material reduction in producing power, and if so, even if it be true that the phosphorus in the second, third and fourth feet participates equally and continuously in crop production, permanent agriculture with undiminished yields must be impossible except through restoration in some manner Professor Hopkins considers that usually there is no natural process of restoration sufficient to maintain high yields, and closes the first part, only after considering crop requirements for nitrogen, phosphorus and potassium, together with sources of plant food, thus providing quantitative data for the discussion of systems of permanent agriculture, treated in seven chapters

In introducing the subject he says:

For practically all of the normal soils of the United States, and especially for those of the central states, there are only three constituents that must be supplied in order to adopt systems of farming that, if continued, will increase, or at least permanently maintain, the productive power of soil. These are *limestone, phosphorus* and *organic matter*. The limestone must be used to

correct acidity where it now exists or where it may develop The phosphorus is needed solely for its plant food value The supply of organic matter must be renewed to provide nitrogen from its decomposition and to make available the potassium and other essential elements contained in the soil in abundance, as well as to liberate phosphorus from the raw mineral phosphate naturally contained in or applied to the soil

It should be said here that throughout the work Professor Hopkins is concerned only with general farming, not with intensive agriculture where other fertilizers can be used with profit and must be if largest results are secured

Chapters are given to the discussion of limestone, of phosphorus and of organic matter and nitrogen, as to their function, quantitative needs and maintenance Then follow chapters on rotation systems for grain farming, live stock farming, the use of phosphorus in different forms and finally theories concerning soil fertility The subject-matter of these chapters is of the greatest importance, the views presented are in the main fundamentally sound, they are well presented and must have a very important influence in advancing agriculture in the United States

Part III contains an admirable digest of the more important field experiments bearing upon permanent agriculture, conducted at Rothamsted, England, in Pennsylvania, Ohio, Illinois, Minnesota, in the south and in Canada, pointing out their bearing upon the views expressed in the preceding sections

Professor Hopkins has succeeded in producing a worthy companion volume to Hilgard's great work "Soils"

The Ice Age in North America and its Bearing upon the Antiquity of Man By G. FREDERICK WRIGHT Fifth edition, revised and enlarged. Pp 800 200 illustrations 8vo, cloth.

The popularity of Wright's "Ice Age" is sufficiently attested by the fact that the fifth edition is now published under date of December 22, 1910, enlarged and embellished with many new and interesting illustrations

The value of Professor Wright's work consists principally in the illustrations and descriptions he gives of glacial phenomena not only in North America, but in other portions of the world The main criticism of this work, which has many good features, is that its author is too credulous, and has thus permitted many exploded "chestnuts" like the Calaveras Skull," the "Lansing Skeleton" and the "Nampa Image" to find in him a defender of their antiquity. This tendency of Professor Wright is unfortunate, since it of itself throws doubt upon his power of critical discrimination in analyzing evidence pro and con in matters of geologic controversy It is possible that Professor Wright's theological beliefs have unconsciously biased his judgment in matters pertaining to the age of the earth and to the date of the glacial epoch In spite of these defects, however, Professor Wright's "Ice Age in North America" will prove a useful work in enlisting popular attention, and study of these most interesting phenomena connected with the Pleistocene glaciation

I C WHITE

SPECIAL ARTICLES

A SCALE FOR MEASURING THE MERIT OF ENGLISH WRITING

ONE inch may be said to be equal to another inch from any one of three lines of evidence If the two are compared by a hundred experts, (1) the experts will all report the two as indistinguishable, or (2) if some of them do, by microscope, micrometer or the like, find a difference of a trifle plus or minus, the number finding the first inch plus will equal the number finding it minus, or (3) if each man is forced to report a difference, half will find the first inch plus and half minus

One specimen of English writing may be said to be equal to another from the second or third lines of argument, the only logical difference between equating the two lengths and equating the two specimens of writing being that the variability of expert judges in the

latter case is so great that we never find all of them, and rarely find many of them in agreement, as to the indiscernibility of any difference. But specimens 571 and 220 below are, in merit as defined by, say, 100 competent persons, approximately equal, since if asked to report 571 as better, equal to, or worse than 220, there will be a large proportion of equals and the judgments "better" will approximately equal the judgments "worse." Of 110 competent persons, forced to make a distinction, 54 favored sample 571 and 56 sample 220.

571. VENUS OF MELOS

In looking at this statue we think, not of wisdom, or power, or force, but just of beauty. She stands resting the weight of her body on one foot, and advancing the other (left) with knee bent. The posture causes the figure to sway slightly to one side, describing a fine curved line. The lower limbs are draped but the upper part of the body is uncovered. (The unfortunate loss of the statue's arms prevents a positive knowledge of its original attitude.) The eyes are partly closed, having something of a dreamy langour. The nose is perfectly cut, the mouth and chin are moulded in adorable curves. Yet to say that every feature is of faultless perfection is but cold praise. No analysis can convey the sense of her peerless beauty.

220. GOING DOWN WITH VICTORY

I sat on the top of a mail coach in Lombard street impatiently awaiting the start. 'Twas the the night of the victory and we would help spread the news over England.

Up jumps the coachman followed by the guard, an instant's preparation, a touch of the lash and we are off! We are soon past the limits of the city out in open country, galloping, tearing along, a clear road ahead of us for the English Mail stops for nothing.

We dash in at villages, stopping but a moment with the mail, shouting the news of the victory and we are off again. Proud were we and had we not a right to be? The first to carry the great news through the land!

The memory of that ride is ever fresh in my mind and I will ever remember those hours as the most glorious in all my life.

The difference between 1 inch and 2 inches is said to be equal to the difference between 2 inches and 3 inches, because the experts will, as before, all agree or divide equally in their disagreement. The essential logic of their procedure will appear if we change the illustration.

Let their task be to examine the following pairs of lengths: I. (*a*) 10.0000 inches, (*b*) 10.0001 inches, II. (*c*) 10.0001 and (*d*) 10.0002, III. (*e*) 10.0001 and (*f*) 10.0003, IV. (*g*) 10.0001 and (*h*) 10.0004, V. (*i*) 10.0001 and (*j*) 10.0005, and to judge in each case whether the second line of the pair is shorter, equal, or longer. We shall find that even the experts make some wrong judgments with these very small differences, but that the proportion of right judgments increases as the difference increases, so that we can conclude that the difference between (*a*) and (*b*) is equal to the difference between (*c*) and (*d*), not because it is always judged so, but because it is *equally often* judged so, by experts. The basis for the scientific acceptance of a difference may then be that judgments of longer are more frequent than judgments of shorter. And the basis for the scientific acceptance of one difference as equal to another difference may be that the preponderance of judgments of longer is equal in the two cases. This is not the whole truth of the matter in the case of the equality of such differences as 1.0001 in. – 1.000 in. and 1.0002 in. – 1.0001 in., but it is a part of it.

This part of it may be made true of judgments of differences in merit in English writing. For instance Specimen 627 is judged to have more merit as writing by young people in their teens than specimen 570 by 83 out of 110 competent persons. Specimen 570 is also judged to have more merit, similarly defined, than Specimen 603 by 82 out of the same 110 competent persons. The difference between Specimens 627 and 570 is then approximately equal to the difference between Specimens 570 and 603.

627. A SCENE

I think the sunlight is very beautiful on the water, and when it shines on the water it is very beautiful, and I love to watch it when it is so beautiful. The colors are so pretty and the noise

of the water with the sunshine are so attractive in the sunshine I wonder do other people love to watch the water like I do I don't know as there is anything as lovely as the water waves in the sunlight of the glorious orb

570 DESCRIPTION OF SCHOOL ROOM

Our school room is on the side of the school house and it is a awfully nice room and I like it because it is so nice and all the boys like it, there is a good many pictures on the wall and there is a clock on the wall We like this school room and come to school most all the time

603 A CHARACTER SKETCH

The man I am describing is a white man and he has nice hair and wears a hat, and his horse is black, I like this man and he has two eyes and his nose is red

In this way it would be possible to discover specimens of English writing ranging from Specimen 607 (which may roughly represent zero merit in English writing by young people in their teens) up to the best writing known, by equal steps, so that Specimens 0, 1, 2, 3, 4, and so on, would have in part, the significance for merit in English writing that 0 inch, 1 inch, 2 inches, 3 inches, and so on have for length

607 SKETCH

I words four and two came go billa gum sing hay cows and horses he done it good he died it goon I want yes sir yes sir oxes and sheeps he come yes sir camed and goes billum gumun oomunn goodum

Such a series of specimens representing defined degrees of merit in composition would be of service to civil service examiners, college entrance examination-boards, high-school teachers of English, and any others who were concerned with measuring ability to write English, the changes produced in that ability by various forms of training, or the differences in it that distinguish certain groups

An investigation designed to establish such a scale is now being made by Mr M. B Hillegas and myself We should be very glad if any of the readers of SCIENCE would cooperate to the extent of sending us their ratings of the ten specimens printed below. All that is required is that the reader consider these as specimens of English writing by young people, choose the one that seems to him to have the least merit, number it 1, choose the one that has next least merit, number it 2, and so on, and send the record to M B Hillegas, Bureau of Education, Washington, D C, or E L Thorndike, Teachers College, Columbia University, New York For this purpose the following slip may be used

I rank specimen 94 as
" " 196
" " 200
" " 300
" " 323
" " 434
" " 519
" " 520
" " 534
" " 627
Signed

94 SULLA AS A TYRANT

When Sulla came back from his conquest Marius had put himself consul so sulla with the army he had with him in his conquest siezed the govern ment from Marius and put himself in consul and had a list of his enemys printy and the men whoes names were on this list we beheaded

196 ICHABOD CRANE

Ichabod Crane was a schoolmaster in a place called Sleepy Hollow He was tall and slim with broad shoulders, long arms that dangled far below his coat sleeves His feet looked as if they might easily have been used for shovels His nose was long and his entire frame was most loosely hung to gether

200

My dear Fred,—

I will tell you of my journey to Delphi Falls, N Y There is nice scenery along this route The prettiest scene is in the gulf which is quite narrow, a small creek flows down it and the road follows along near its banks

There are woods on either side, these trees look very pretty when they are white with snow

In summer it is always shady and cool in them and the small fish may be seen darting back and forth in the water

I hope I will have the pleasure of taking you over the route some time.

Yours sincerely,

300 THE PREACHER OF AUBURN

The most popular man of Auburn was the preacher Although he had a very small salary he was contented The preacher was kind to everybody Little children loved him Old soldiers liked to sit by his fireside and tell stories of the battles, which they had fought in The beggars who came to his door, although chided for leading such an existence, were always clothed and feed

The preacher was always willing to go to the homes where there was sickness or death Here he helped in all things that he could

In the church he preached with unaffected grace, and all who came to scoff at him remained to worship

The minister was a contented, simple and kind man, whom the people loved

323 ESSAY ON BURNS

As far as I can learn from the Essay on Burns, Mr Carlyle considers that good poetry must contain the sincerity of the poet The poem must show the author's good choice of subject and his clearness of sight In order to have good poetry the poet must be familiar with his subject and his poem will show it

The characteristics of a great poet, in Mr Carlyle's opinion were sincerity and choice of subjects A poet must be appreciative of nature and have a responding heart Carlyle says a true poet does no have to write on subjects which are far away and probably come from the clouds A truly great poet makes the most of subjects which are familiar to him and close to earth, as Burns did in his poems to the Field Mouse and to The Daisey

434 A DIARY

I had an early run in the woods before the dew was off the grass The moss was like velvet and as I ran under the arches of yellow and red leaves I sang for joy, my heart was so bright and the world was so beautiful. I stopped at the end of the walk and saw the sunshine out over the wide "Virginia meadows"

It seemed like going through a dark life or grave into heaven beyond A very strange and solemn feeling came over me as I stood there, with no sound but the rustle of the pines, no one near me, and the sun so glorious, as for me alone It seemed as if I felt God as I never did before, and I prayed in my heart that I might keep that happy sense of nearness all my life.

519 DE QUINCY

First De Quinceys mother was a beautiful women and through her De Quincy inhereted much of his genius

His running away from school enfluenced him much as he roamed through the woods, valleys and his mind became very meditative

The greatest enfluence of De Quincy's life was the opium habit If it was not for this habit it is doubtful whether we would now be reading his writings

His companions during his college course and even before that time were great enfluences The surroundings of De Quincy were enfluences Not only De Quincy's habit of opium but other habits which were peculiar to his life

His marriage to the woman which he did not especially care for

The many well educated and noteworthy friends of De Quincy

520 A CHARACTER SKETCH

They were in fact very fine ladies, not deficient in good humour when they were pleased, nor in the power of being agreeable when they chose it, but proud and conceited They were rather handsome, had been educated in one of the first private seminaries in town, had a fortune of twenty thousand pounds, were in the habit of spending more than they ought, and of associating with people of rank, and were therefore in every respect entitled to think well of themselves, and meanly of others

534 FLUELLEN

The passages given show the following characteristic of Fluellen his inclination to brag, his professed knowledge of history, his complaining character, his great patriotism, pride of his leader, admired honesty, revengeful, love of fun and punishment of those who deserve it

627 A SCENE

I think the sunlight is very beautiful on the water, and when it shines on the water it is very beautiful, and I love to watch it when it is so beautiful. The colors are so pretty and the noise of the water with the sunshine are so attractive in the sunshine I wonder do other people love to watch the water like I do. I don't know as there is anything as lovely as the water waves in the sunlight of the glorious orb

SEX-LIMITED INHERITANCE AND SEXUAL DIMORPHISM IN POULTRY

WHEN a Barred Rock hen is bred to a non-barred, *e. g.*, black, cock, all the female offspring are non-barred, all the male barred. This generation, then, is sexually dimorphic. The offspring of the reciprocal mating is not dimorphic, since all the offspring are barred. For reasons which will appear in a moment, I wish to repeat the usual formulæ for this case, B standing for barred, b for non-barred, *e. g.*, uniform black.

Barred Rocks: male, B♂ B♂, female, B♂ b♀.
Non barreds: male, b♂ b♂, female, b♂ b♀.
A. Barred females by non barred male gives in F_1,
barred males, B♂ b♂, gametes, B♂ b♂,
and non barred females, b♂ b♀, gametes, b♂ b♀.
Inbred they give in F_2, barred males, B♂ b♂,
non barred males, b♂ b♂,
barred females, B♂ b♀,
non barred females, b♂ b♀.
B. Non barred females by barred male give in F_1,
barred males, B♂ b♂, gametes, B♂ b♂,
and barred females, B♂ b♀, gametes, B♂ b♀.
Inbred they give in F_2, barred males, of two sorts, viz. $\left\{\begin{array}{l}\text{B♂ B♂,}\\ \text{B♂ b♂,}\end{array}\right.$
barred females, B♂ b♀,
non barred females, b♂ b♀.

Now barring is a dominant character. If, however, it is treated as a recessive, *i. e.*, patent only in the homozygous condition, some suggestive results follow. In the first place the Barred Rocks become sexually dimorphic in respect to barring, for the male, being homozygous, will be barred, but the female being heterozygous will be non-barred. Moreover, this dimorphism will continue indefinitely in succeeding generations.

When this hypothetical dimorphic breed is bred reciprocally to a uniform black breed, all the F_1 offspring will be non-barred and the usual signs of sex-limited inheritance will be lacking. The F_2 generation, as shown under A, will all be non-barred, and of those under B only one fourth will be barred and these all males.

This hypothetical case offers a plausible explanation of the mode of inheritance of sexual dimorphism. However, this case, while possible, is probably simpler than any likely to be encountered in actual experience. Moreover, the greater the number of different factors involved, the more the observed ratios will obscure the hypothetical ratios.

The following experiments are interesting in this connection.

First may be recorded the results of crossing Brown Leghorns and Buff Plymouth Rocks. The former's plumage or some of its elements is known to follow a sex-limited mode of inheritance. Of the mating Buff Rock females by Brown Leghorn male only chicks in the down are on hand but they are exactly like the chicks of the reciprocal mating. The adults of this last mating are reddish buff in both sexes without the usual features of sex-limited inheritance. In F_2 true buffs appeared and various other colors (among them the Rhode Island red color) but no true Brown Leghorns. The detailed theoretical formulation must await the results of other matings, but compare under A above. Chicks in the down of the mating F_1 female by Buff Rock male are on hand. None of these, unlike many of the F_1 chicks, are striped. The absence of striped chicks indicates an absence of the heterozygous form.

In the second place are to be recorded the results of castration experiments on young Brown Leghorns. Though not yet old enough to show all the adult characters, the castrated males are assuming the male juvenile plumage, which, it should be noted, is almost as sharply differentiated from the female's juvenile plumage as the adult male's is from the adult female's. The castrated females, on the contrary, have already assumed a considerable part of the male's juvenile plumage.

These experiments indicate that a recessive character, sex limited in inheritance, can, according to the formulæ given above, be utilized in an explanation of the mode of inheritance of sex dimorphism. On the other hand, a dominant sex-limited character, at least in poultry, does not lead in this direction.

While it is probable that the plumage of the male Brown Leghorn is a homozygous recessive, and the female heterozygous, it is

not certain what the dominant element or factor is It may be female Brown Leghorn color, a modifier, or femaleness or something else As females colored nearly like Brown Leghorn females appeared among black females in F_1 from Brown Leghorn males by White Rock females it suggests that the dominant element is not female color

A similar inference may be drawn from the distribution of color in the buff and black nonbarred F_1 females from White or Barred Rock females by Buff Rock male Some of these are black with orange hackle and grade into others in which buff predominates In all cases the colors are distributed in a more or less perfect imitation of the pattern of Brown Leghorn females Moreover, many of these hybrids are stippled in certain regions which always correspond to the regions in Brown Leghorns which are stippled

THE NORTH CAROLINA ACADEMY OF SCIENCE

The tenth annual meeting of the North Carolina Academy of Science was held at the Agricultural and Mechanical College, Raleigh, on April 28 and 29, 1911, with an attendance of forty members The meeting of the executive committee, held in the early afternoon of April 28, was followed by a general meeting for the reading of papers At night, after the academy had been welcomed to the Agricultural and Mechanical College by President D H Hill, the retiring president of the academy, Professor W H Pegram, delivered his presidential address, "The Problem of the Constitution of Matter" Following this, Professor John F Lanneau gave a lecture on "Sirius. the Bright and Morning Star."

On Saturday morning, April 29, the annual business meeting was had Reports of the secretary-treasurer and of the various committees were made. Five new members were elected These together with the present membership of 80 give a total of 85 members The report of the secretary treasurer showed that the academy in membership, in the interest shown in its work, and in its finances, was in better condition than at any time during its history.

The following officers were elected for the ensuing year

President—H V Wilson, University of North Carolina, Chapel Hill

Vice president—W A Withers, Agricultural and Mechanical College, West Raleigh

Secretary treasurer—E W Gudger, State Normal College, Greensboro

Executive Committee—J J Wolfe, Trinity College, Durham, Franklin Sherman, Jr, Department of Agriculture, Raleigh, Andrew H Patterson, University of North Carolina, Chapel Hill

At 10 A M the academy and the North Carolina Section of the American Chemical Society held a joint meeting at which Dr R A Hall, of the University of North Carolina, read a report on "The Chemical Researches of Ehrlich Leading to '606'" Following this, reading of papers on the academy program was resumed At 2 P M, the program being finished, the academy adjourned to the dining room of the college, where a luncheon was given complimentary to the visiting members

The total attendance was forty out of a membership of eighty five There were thirty three papers on the program, all of which were read save two, and all read when called for but two In attendance, number of papers presented, general interest as evidenced by the discussion of the papers, this session excelled any in the history of the academy In addition to the presidential address, which is published in full in the current number of the *Journal of the Elisha Mitchell Scientific Society*, and to the lecture on Sirius, the following papers were presented

Catching Hawk Moths on Flowers at Dusk C S Brimley, Raleigh

This paper tells the author's experiences in catching hawk moths on flowers at dusk in several years at Raleigh, N C The flowers first experimented with were jimson weed, afterwards four-o'clocks With the jimson weeds it was found that tying the flowers in bunches was an advantage, while this did not apply to the four-o'clocks, as they were already in bunches Two flights of moths were noted, the first in June, the second in July and later, the latter largely, the former wholly composed of moths from over wintering pupæ. The proportion of sexes visiting flowers was 5 males to 2 females. A neighbor's cat was found to be as expert a catcher of hawk moths on flowers as the author The notes apply mainly to the two tobacco hawk moths.

To be published in full in the current number of the *Journal of the Elisha Mitchell Scientific Society*

Natural History Notes E W GUDGER, State Normal College, Greensboro

A *An Interesting Case of Symbiosis* (specimens exhibited) —For six successive seasons, wood frogs, leopard frogs, toads and salamanders (species unknown, probably *Amblystoma punctatum*) have been observed to lay their eggs in a small pool in the college park Each spring it has been noted that the eggs of the salamanders only had a greenish color Microscopic examination shows that this is due to great numbers of a very small unicellular green alga found within the inner mass of jelly The green color grows more marked as the development of the eggs takes place, due presumably to the larger amount of CO_2 given off as the larvæ become more active Since no algæ have ever been found in the outer or general mass of jelly, it seems possible that they may penetrate the oviducts of the salamander and become enclosed in the inner capsule of jelly as the eggs pass to the exterior

B *Some Plant Abnormalities*—A bifurcated frond of the common Boston fern was exhibited This was one of two growing on one plant in the writer's laboratory at the present time Three years ago two others were noticed on different plants

A drawing was exhibited of a motile *Hæmatococcus* with four flagella This was found last fall in a lot of fresh material from a cemetery urn

Conjugating Yeasts W C COKER, University of North Carolina, Chapel Hill

In the course of experiments by an advanced class in the fall of 1910 the rare and peculiar wild yeast, *Schizosaccharomyces octospora* Beyerinck, was found It appeared in test tubes that were filled with distilled water in which were a number of unbroken Delaware grapes that were bought in the local market A day or two after the tubes were prepared a slow fermentation set up, and later a precipitate appeared On examination of this precipitate after three weeks it was found to contain the *Schizosaccharomyces* in process of conjugation A later experiment made with Tokay grapes gave a similar result Cultures were continued and the life history studied in all stages, confirming in general the observations of Guilliermond. Four species of *Schizosaccharomyces* ,are known, all supposed to be tropical or subtropical, and *S octospora* has not been found before in America

Results of a Practical Attempt to Control Lettuce Sclerotiniose F L STEVENS, North Carolina College of Agriculture and Mechanic Arts, West Raleigh

Lettuce sclerotiniose has been the subject of investigation for several years in the North Carolina Agricultural Experiment Station From the laboratory study it was concluded that all structures except the sclerotium are short lived, therefore, that if the formation of new sclerotia could be prevented diseased beds could eventually be restored to health To test this theory several experimental beds were very thoroughly infected in April, 1908, by heavily inoculating a large number of plants and allowing the sclerotia which were formed to remain in the beds The following year 555 plants, or over 45 per cent, died of sclerotiniose From this time on a course of treatment designed to prevent the forming of sclerotia was followed with the hope of lessening the disease The following year only seven plants, or one half of one per cent, of the crop died A year later, that is, the present year, the results were almost the same This experiment seems to indicate that control of this disease can be obtained by the methods employed

Studies in Soil Bacteriology, V—The Nitrifying Powers of North Carolina Soil F L STEVENS and W A WITHERS, assisted by P L GAINEY, F W SHERWOOD and T B STANSEL

During 1909 and 1910 samples were taken from 58 localities representing 21 different soil types, in each of which was a good soil and a poor soil. The soils came from sixteen counties Nitrification was expressed as N E, N I P and N I P in Solu, which terms have been explained in previous publications[1]

A summary of the results is

	N E	N I P	N I P in Solu
Maximum found	105 1	89 9	1 5
Average for good soil	8 7	44 7	0 6
Average for poor soil	5 0	34 8	0 6
Average for all soils	6 8	39 8	0 6

There is seen to be a great difference in results by different methods of testing There is also a difference between the results obtained by the same method on samples taken from the same

[1] *Centralblatt f. Bakt*, Abt II, Bd 25, 1910, p 64

field if the two samples are taken a year apart. N. I. P. in soil gave the higher results on an average, but not always in individual cases, showing that our soil 1931, which has been used so much, affords better conditions for nitrification than most of our soils.

N. I. P. in solution shows no correlation with fertility. N. I. P. in soil shows better nitrification with the good soil in 69.2 per cent. of the pairs. N. E. shows no nitrification in either the good or poor samples in 29.6 per cent. of the pairs, but where there is nitrification it shows better in the good in 63.2 per cent. of the pairs. There are several samples in which the poor soil shows better N. E. and N. I. P. than the good soil.

Some Points on Architectural Acoustics: ANDREW H. PATTERSON, University of North Carolina, Chapel Hill.

An account of experiments made by the author and Mr. A. L. Field on the acoustics of Memorial Hall at the University of North Carolina. The reverberation in this hall is very bad, and the problem is complicated by bad echoes due to large flat panels in the dome-shaped ceiling. Further experiments will be undertaken in an attempt to find a complete solution of the difficulty.

Preliminary Report on the Regeneration of Nemerteans and Amphitrite: JUDSON D. IVES, Wake Forest College, Wake Forest, N. C.

Sections of nemerteans were found to regenerate readily and rapidly. But little new material formed on the anterior surfaces. Small sections, not more than 1.2 cm. long, in twenty-five days regenerated 2.5 cm. on their posterior surfaces. A section, 2.1 cm. long, regenerated 1.5 cm. in twenty-five days. A worm, with its posterior portion cut off, its head and the remaining anterior portion measuring 10.2 cm., regenerated 1 cm. in twenty-nine days.

In Amphitrite, the tentacles regenerate readily. Worms, with the portion in front of the second pair of branchiæ removed, thereby removing the tentacles and the first pair of branchiæ, lived for thirteen days, and were in good condition when killed.

A Dangerous Apple Disease: F. L. STEVENS and GUY WEST WILSON, North Carolina College of Agriculture and Mechanic Arts, West Raleigh.

This disease came to our notice in 1909 from Lincoln County, where it appeared in 1908 on a single tree and despite the cutting out of all disease seen and spraying with lime-sulphur it spread the next year to thirteen trees. The same trouble appeared in Sampson County in 1909 with even more disastrous results.

Whitish or pinkish pustules appear on the younger twigs and about the crotches of the tree. These bear numerous spores of the *Fusarium* or *Tubercularia* type, but so far no ascigerous form has been connected with them. The infection is in the bark, the diseased areas shriveling and separating. The epidermis splits away, exposing the browned surface beneath, or the pustules merely break through the epidermis, especially near the lenticels. Upon older twigs the bark cracks longitudinally, exposing rows of pustules in the cracks. A pinkish mycelial growth sometimes appears on the diseased twigs.

Condimental Feeds, Stock and Poultry Tonics and Conditioners: G. M. MACNIDER, Department of Agriculture, Raleigh.

A review of the work done by the author on proprietary stock and poultry medicines, the results of which have been published in full in a recent bulletin of the North Carolina Department of Agriculture.

Sixty-four preparations were analyzed chemically and microscopically. They were found to be composed largely of a base material such as cotton-seed meal, oil meal, wheat bran, etc., with small amounts of drugs added. Thirty-four drugs were identified in the preparations examined. The ones used in largest amount are practically worthless as medicines, while those that are of value are used in such small amount that they can have no effect.

The Turkey Buzzard Must Go: GEORGE W. LAY, St. Mary's School, Raleigh.

Originally "the birds of the air and the beasts of the field" were the recognized scavengers. The dog even now is so used in oriental countries, but in a higher civilization his services have been superseded by more modern methods.

The turkey buzzard spreads diseases such as chicken pox and hog cholera chiefly by infection carried on the feet. Owing to his great range of flight he carries disease from the point of infection to places far distant. If burial, the proper method for disposal of dead bodies, is used, he becomes a predatory bird, killing chickens, young pigs, etc. He is therefore a dangerous bird and should no longer be protected by law.

To be published in full in the current number of the *Journal of the Elisha Mitchell Scientific Society*.

The Library of Congress as an Aid to Scientific Research E. W. GUDGER

The Library of Congress, with its vast aggregations of books and journals, including the priceless Smithsonian collection, is the greatest aid in America to the historical side of scientific research. Through the system of inter-library loans, nearly any and all of this enormous mass of literature is available to the scientific researcher, provided that his college library bear the cost of transportation. The writer has during the past five years carried on three separate extensive historical researches in ichthyological literature which would have been impossible without access (at a distance) to this great library. It is a pleasure to record the prompt and efficient service with which every one of many requests for books has been met, and to call the attention of scientific men to this great adjunct to their work.

Occurrence of the Yellow Fever Mosquito at Raleigh C. S. BRIMLEY, Raleigh

In the summer of 1910 the writer found a rather small mosquito with white banded legs to be common in his house in the daytime. On investigation this proved to be *Stegomyia calopus*, the species which transmits yellow fever. The species was active all day, biting even at noon in a well lighted room, while mosquitoes taken after dark almost invariably turned out to be other species. The species has not been taken by other Raleigh entomologists. No breeding places were discovered.

Proposed Reform in our Calendar ANDREW H. PATTERSON, University of North Carolina, Chapel Hill

A discussion of the various methods proposed in recent years for the reform in our present calendar.

Some Interesting Water Molds W. C. COKER, University of North Carolina, Chapel Hill

The occurrence in Chapel Hill of *Thraustotheca clavata* (DeBary) Humphrey was reported. It seems to have been found previously only at Strassburg, Germany. In this singular mold the sporangial wall dissolves away almost completely, suggesting the method of spore liberation in *Rhizopus*, and the encysted spores are allowed to fall apart in all directions. The spores escape from their cysts in the laterally ciliated form, showing that the first swimming stage is suppressed.

There also occurs in Chapel Hill a species of *Dictyuchus* in which the entire sporangium breaks away from the hypha as soon as the spores become distinct. After some time the spores escape singly through individual tubes as is normal in the genus. Other points reported were the appearance of a variety of *Achlya americana* with hypogynous tubes, the occurrence in Chapel Hill of *Achlya racemosa* Hildeb., and the fact that *Saprolegnia diclina* Humphrey is at least not always diœcious.

Rhizoctonia of Buckwheat F. L. STEVENS and G. W. WILSON, North Carolina College of Agriculture and Mechanic Arts, West Raleigh

Mention was made of a serious outbreak of rhizoctoniose on buckwheat in the western part of North Carolina.

The Finned-tailed Larva of the Butterfly Ray, Pteroplatea maclura E. W. GUDGER

The adult ray has a very short tail, in length about equal to one third of the body, with very faint traces of dorsal and ventral finfolds. A photograph was exhibited of three young attached to flattened yolks, showing each embryo with a profusion of long external gills and a tail three fourths as long as the body. All three larvæ have the hinder halves of their tails distinctly finned above and below, thus forming broad paddle-like organs. The significance of this in the phylogenetic history of this ray is very great.

More than half the material is at hand for the embryology of the fish, and an effort will be made to collect the remaining stages this season.

The Whistling Arc in the Study of Auditorium Acoustics C. W. EDWARDS, Trinity College, Durham

Employing the well-known device of using a sound-emitting light for a source of sound waves, a whistling arc was used for investigating confusion and distortion in an auditorium. The very large variety of sharp clear notes that the arc could be made to emit by varying the inductance made it especially useful in the study of the less practical problem of distorsion. Small mirrors were used, following the method of F. R. Watson, of the University of Illinois, to trace the path of the sound waves after reflection from various surfaces.

SOCIETIES AND ACADEMIES

THE AMERICAN PHILOSOPHICAL SOCIETY

AT the meeting of the American Philosophical Society, Philadelphia, on May 5, 1911, an address on lignite was delivered by Dr. Joseph A. Holmes, director, Bureau of Mines, Washington, D. C.

The extent of the lignite deposits in the United States will be realized from the following figures giving the areas in several of the states:

Alabama	6,000
Tennessee	1,000
Louisiana	8,800
Arkansas	5,900
Texas	53,000
South Dakota	4,000
North Dakota	31,000
Montana	7,000

In a number of states in the Rocky Mountain region there are large areas of coal that represents a transition between typical lignites and bituminous coals. For these the name "sub-bituminous coals" has been suggested, and is tentatively used by the United States Geological Survey.

The lignite beds in Alabama, Mississippi and Tennessee represent a transition between peat and the more typical lignites of the Dakotas and Texas. Little or no use has been made of the lignite beds in these three states.

The lignites in Texas and Arkansas have been used to a limited extent, as have also the lignites of the Dakotas and eastern Montana. In this latter field the lignites contain 20, and in some cases more than 40, per cent. moisture, and slack badly and rapidly on exposure to the atmosphere, and this quality seriously interferes with their use and value for fuel purposes.

The outlook for the utilization of lignites is favorable along three lines: (1) In gas producers, without either drying or other treatment; (2) in boilers of special construction, such, for example, as that installed more than a year ago at Williston, N. D., by the United States Reclamation Service, where the lignite is used in its natural condition almost immediately after being brought from the mine; (3) in the form of briquettes. This requires that the lignite should be thoroughly and finely crushed and dried to a moisture content of from five to ten per cent., and then compressed while still warm into briquettes.

Limited quantities of lignite from California, North Dakota and Texas have been made into satisfactory briquettes at the Government Mine Experiment Station at Pittsburgh, using the full-sized German briquetting press, which develops a pressure of twenty to twenty-five thousand pounds per square inch. In the cases just mentioned the briquettes were made without the use of any binding material, a sufficient amount of tarry material remaining in the crushed and dried lignite to serve as a bond to hold the particles together in the briquette.

It is believed that our investigations along this line will demonstrate the fact that the lignite in Texas, and the Dakotas and Montana can be made into briquettes on a commercial scale, and that in this form the lignite can be used as a substitute for other domestic fuel in these regions.

NEW REQUIREMENTS FOR ENTRANCE AND GRADUATION AT THE UNIVERSITY OF CHICAGO

THE University of Chicago faculty has just adopted a new plan for entrance to the colleges and a new set of requirements for graduation with the baccalaureate degree, which represent the results of some two years or more of careful study. The original motives for the investigation were several. On the one hand, it was felt that the university was in some essential particulars losing touch with the secondary schools from which its undergraduate student body is recruited. This feeling was not based upon loss of numbers, for these have steadily increased, but in part upon the expressions of the principals and teachers in these schools, and in part upon the considerable number of conditioned students who were received year by year. On the other hand, the faculty has been called upon constantly to consider requests from students to be relieved from certain of the requirements for the bachelor's degrees. The character of these requests made it clear that to some extent at least the curricula of the university were not meeting the reasonable needs of students, nor contributing in the most effective way to their serious education. Too little opportunity was afforded to meet the demands of training for special careers lying outside the usual forms of business and the learned professions. Especially was this maladaptation recognized in the case of women students, for whom it seemed at times desirable to devise special courses of study designed to fit them for particular lines of work. Other matters

might be mentioned which were responsible for the original determination to study the entire situation, but these will suffice to indicate the points of departure As the work progressed it became increasingly evident that nothing short of a drastic reconstruction of the whole principle upon which the requirements of the university were based would adequately meet the necessities of the case

For a number of years past the university has maintained a list of approved schools from which it admits students upon proper certification The test which the schools have been obliged to meet has been that of personal inspection by a competent examining officer This will still be the practise when a school is put upon the list for the first time This is substantially the system in general use throughout the central portions of the country The university proposes now to make a radical departure which involves shifting the emphasis from the examination of the school to a test of its work as judged by the records of its students after they come to the university From this time on carefully tabulated records will be kept, showing the work of each student The authorities of the school from which he comes will be periodically informed of these records and the teaching in the school will be judged accordingly. As an interesting supplement to this plan, it is hoped from time to time to bring teachers from the approved schools to the university to visit those classes which continue the work done in the schools In this way it is expected to bring about a more intelligent cooperation than has hitherto been possible Ordinarily the college inspects the schools We propose, in addition to this, that the schools shall inspect the college. We believe that if this be done in the cordial spirit which has hitherto characterized our relations to the schools, both the university and the schools will be markedly benefited

The university appreciates the vital significance of the development which has been in progress in the high schools of the country during the last decade It sympathizes most cordially with the effort which these schools have been making to furnish, each to its own community, those things most essential to the betterment of the life of that community It recognizes that amid the enormous variety of conditions in American life, schools in different localities, even schools in different portions of the same city, may face obligations in certain essentials widely divergent, to meet which successfully must involve considerable variation in curricula and methods of work The university desires to do nothing which will in any way thwart the fullest success of this tendency in the modern high school The period of sheer dictation by the college to the high school is forever passed Possibly there is at the present time a danger that the schools may, in their turn, attempt to dictate to the college However this may be, the University of Chicago desires and intends to put itself in the position of cooperating in the most effective way with those high schools which are earnestly striving to meet the needs of their communities It desires to leave them the utmost flexibility in the arrangement of their curricula compatible with the carrying forward by the university of solid and serious work, which obviously must have its foundation in the achievements of the school. The college entrance plan shortly to be described has this end as perhaps its most important aim

In compensation for the increased flexibility which the new arrangement permits, the university hereafter will expect to ad-

mit no student with less than fifteen units of entrance credits In other words, entrance with condition is to be abolished

The most striking change in the actual character of the requirements—matters of principle apart—is found in the substitution of certain specifications regarding the *amount* of work which a student must bring to the university as counter-distinguished from the particular subjects in which the credits must be offered The *quality* of the work we expect to test chiefly by the college record of the students Hitherto, following the practise of most colleges, the university has designated so much of this subject, and so much of that, as a requisite for entrance With a single exception, this type of requirement now gives way to a demand for a certain amount of concentrated and continuous work in subjects selected by the student, or by the school, from among the standard academic subjects taught in all high schools The one stipulated subject which must be presented is English, and this is required on the ground of its unique relation to all other subjects in the curriculum

Quoting from the requirements themselves:

Students applying for entrance to the University of Chicago present by certificate from approved schools, or by examination, 15 units of entrance credits. Among these must be 3 units of English and in addition one principal group of 3 or more units, and at least one secondary group of 2 or more units These additional groups may be selected from among the following subjects

1 Ancient languages (Greek and Latin), it being understood that to make a group of 2 or of 3 units the work must be offered in a single language

2. Modern languages other than English, to make a group of 2 or of 3 units work must be offered in a single language as under group one.

3. Ancient history, medieval and modern history, English history, United States history, civics, economics.

4. Mathematics.

5 Physics, chemistry, botany, zoology, general biology, physiology, physiography, general astronomy

Not less than 1 unit may be offered in either physics or chemistry Any combination of the subjects within each group is permitted

Of the 15 units offered for entrance not less than 7 must be chosen from subjects in groups 1–5 (or 10 including English) Not less than one half unit may be offered in any subject

The remaining 5 units may be selected from any subjects for which credit toward graduation is given by the approved school from which the student receives his diploma, but Greek, Latin, French, German (and all modern languages other than English), mathematics, physics and chemistry, if offered, but not as above under 1 and 5, must each consist of at least 1 unit Latin may not be continued in college unless at least 2 units be offered

It will be noted that a student may be admitted without having taken any work in three of the groups, provided he has had enough work in the other two, and that the content of 5 units is left entirely to the secondary schools, the only restriction being that they accredit the work toward their own diploma The university is confident that such freedom in admission will in no way impair the standard of its degrees, because for several years a rigid method of grading has been in force, by which inefficient students are inevitably eliminated very early in the course

The first two years of the college course are designed to articulate in the most intimate way with the high school course, and to assure certain results by the end of the second year of college residence, such as may enable the student at, or before that time, to enter with the greatest advantage upon professional specialization of one kind or another, and to make certain that each student, whether consciously aiming at a particular vocation or not, shall before graduation have acquired a reasonable mastery of one or more fields of knowledge.

To secure an effective correlation of

the high school and the college work it is provided that throughout the first year of his college residence the student shall pursue one subject which he has pursued in the high school either for two or for three years, or which he has pursued throughout the whole of the final year of his school course. The student will be encouraged to choose the last alternative only in cases where it is fairly certain that this subject is to constitute one of the important lines of specialization in his college work. Were either of the first two alternatives adopted, which would perhaps most often occur, the result would be to assure by the end of the first year a considerable proficiency in some one subject. It will be remembered that the entrance requirements were designed primarily to assure the gaining of a satisfactory amount of concentration in some two or more lines of work without particular reference to the special subjects in which such concentration was demanded. The requirement just described for the first year of college is intended to carry forward this principle of concentration, and to secure the two-fold result of bridging the gap between the college and the high school in a subject with which the student is already reasonably familiar, and also to secure at a relatively early stage of the college course the intellectual advantages which are gained by a considerable mastery of some one topic.

The college requirements fall into two main groups, those which are to be fulfilled during the first two years of the course, and those which are to be fulfilled before graduation, and chiefly during the final two years of residence. For a number of years the university has conferred a title known as the associate's title upon students who have completed with a certain degree of excellence the first two years of the college course. This title will still be conferred in accordance with the following plan.

In conjunction with the requirements for the "continuation work" in the first year are those now to be described which extend over the first and second years. During this period two courses in English and one in public speaking must be taken. The student is also obligated so to arrange his work that either in the high school or in the first two years of college he shall have completed the equivalent of two units in each of the following four groups of subjects: (1) Philosophy, history, social science, (2) modern language other than English, (3) mathematics, (4) science, physical or biological.

The English requirement is simply a continuation of the one which the university has administered for a number of years, and which experience apparently justifies. It is designed primarily to equip the student with a satisfactory command over the written and the spoken form of his mother tongue.

The distributive "group" requirement is obviously designed to assure the possession by each student of at least a rudimentary acquaintance with each of the great typical fields of knowledge. It will be readily understood by those familiar with high school curricula, that a student in a well equipped school might easily fulfill this group requirement before entering college. If this be not done, however, the discrepancy must then be made good before the end of the second college year.

The requirement in modern language is intended to assure the student a practical reading knowledge of some one modern language. This capacity will be tested by suitable examinations in the case of students who enter the university with credits for the required amount of language; or the successful passing of an advanced

course with a standard of excellence distinctly above the passing mark will be regarded as satisfying the requirement

In general, then, it is intended that by the end of the second college year the student shall have secured a reasonable mastery over some one field of the work which he brings in from the high school, that he shall have come in contact with all the main divisions of knowledge, and that he shall be in possession, for purposes of practical use in his work, of at least one of the modern languages other than English.

Requirements for the bachelor's degree, in addition to those for the associate's title, involve the completion by the student of a principal and a secondary sequence of coherent and progressive courses The principal sequence must consist of nine such courses, each occupying either 48 or 60 hours of class work [double this amount in the case of laboratory courses] The secondary sequence must contain six such courses in another subject It will be understood that the student is obliged to present a full four years of work at a certain standard grade It may also be added that should a student decide to choose one of his sequences in the subject which he pursued as a continuation course in his first year, the three courses taken at that time may be included in the total number required to make up the sequence. This requirement is intended to secure a high degree of specialization in at least one subject of the university curriculum, with a lesser degree of concentration in some secondary topic, which might often be distinctly supplementary to the first The university has for a number of years had a nine major requirement for its S.B degree, and its experience with this plan affords a high measure of confidence that the new proposals will prove extremely efficient in obtaining substantial results

Under normal circumstances, students will be left slightly less than one third of their courses in high school and in college open to free election The more judiciously the school course were arranged, the larger would be the number of free electives in college Ordinarily not more than fifteen full courses may be taken in college in any one department

When the principal sequence is taken in the department of science the S B degree is conferred When it is in the modern languages or the social and historical sciences, or in philosophy, the Ph B degree is conferred The A B degree is conferred when the two sequences are respectively in Latin and Greek In this case the exact amount required varies somewhat from the other instances, and the requirement must be in part fulfilled in the preparatory school The general plan, however, is exactly the same as in the case of the other degrees, and the detailed provisions need not be explained in this place The university has conferred these three degrees for a number of years

A large number of alternative sequences will be worked out, designed to meet in the most effective way a variety of student needs Students contemplating a professional career in law or in medicine will have sequences offered to them prepared with special reference to these professions The same thing will be done for students whose needs are of a different character It is also contemplated that any student who is able to present to his dean at an early stage in his college work sequences of an educationally defensible kind, other than those prepared by the faculty, may, upon securing permission from the college board, be allowed to pursue such courses It is hoped that in this

way adequate provision may be made for the larger vocational interests represented by college students of serious purpose and well matured plans. An inspection of the provisions will at once make clear that the conception of vocational training is broad and catholic, and not in any way to be identified with the occasionally narrow and shallow training afforded by so-called vocational schools.

JAMES ROWLAND ANGELL
THE UNIVERSITY OF CHICAGO

THE MAN OF SCIENCE AND HIS DUTIES[1]

I HAVE been laboring with some uncertainty, in an effort to determine what would be most suitable for an occasion of this kind. Shall I read a text, or shall I sound a key-note? Perhaps either or both would be in harmony with the occasion. For it is the aim of this society to promote what I consider the highest interests of mankind. We are to give every possible encouragement to those who seek to widen the boundaries of human knowledge. The world is beginning to learn how all-important it is that this should be done. We no longer need to spend any time in contending for such ideas. We only need to ask the doubter to read history, and to open his eyes to his surroundings. The boundary of human knowledge has been widening in a way that must excite our wonder. Like the four sages, of whom Dante has given us a beautiful picture, we stand in the hemisphere of light that has been kindled in our midst, and which slowly pushes back the surrounding darkness. But this only serves to reveal, more and more, the immensity of the region of darkness which still lies beyond. I wish to emphasize on every proper occasion, and certainly on this occasion, that the men who have earned and deserve the peculiar and special gratitude of their successors, are the men who could by no means foresee the value of their work.

Think for a moment of what the world owes to Michael Faraday. He never suspected the value of his work. The most learned men of his day were interested in his results, but they could not foresee their value. He was a man who had none of the advantages which a college student of to-day so often neglects. The son of a blacksmith, he was apprenticed to a bookbinder. While at this labor, he attracted the attention of Sir Humphry Davy, who was in charge of the laboratories of the Royal Institution. And this institution, by the way, was founded by a former teacher in a New England school, who became Count Rumford, and who was one of the greatest men that America has produced.

Faraday became the assistant of Davy, and he remained in the institution for fifty-four years. At the age of forty-two his merits were recognized by the governing board, in an action which relieved him of all lecture and instruction work. This was also a recognition of an obligation which they owed to the world.

Consider the results of one fragment of his work. On September 22, 1831, two years before he was relieved of instruction duties, Faraday wrote in his note-book as follows:

> I have had an iron ring made (soft iron), iron round and ⅞ of an inch thick, and ring six inches in external diameter. Wound many coils of copper round one half of the ring, being separated by twine and calico. There were three lengths of wire, each about 24 feet long, and they could be connected as one length or as separate lengths. By trial with a trough, each was insulated from the other. We will call this side of the ring *A*. On the other side, but separated by an interval, was wound wire in two pieces, together amounting

[1] Address of the president of Washington Chapter Sigma Xi.

to about 60 ft in length, the direction being as with the other coils This side call *B*

Charged a battery of ten plates, four inches square, made the coil on *B* side one coil, and connected its extremities by a copper wire passing to a distance and just over a magnetic needle (three feet from iron ring) Then connected the ends on one of the pieces on *A* side with the battery immediately a sensible effect on needle It oscillated, and settled at last in original position On breaking connection of *A* side with the battery, again a disturbance of the needle

Later he varied the experiment and writes:

In place of the indicating helix, our galvanometer was used, and then a sudden jerk was perceived when battery communication was *made* and *broken*, but it was so slight as to be scarcely visible It was one way when made and the other way when broken, and the needle took up its natural position at intermediate times

The device which Faraday described was a transformer The impulses which he saw in the needle were due to induced currents He was at once led by this to the invention of the first dynamo, which he constructed during the same month

If any person had asked Faraday that exasperating question, what is all this worth in pounds, shillings and pence, or what are your services really worth per student hour, he would have been utterly unable to make a satisfactory reply The effects were so minute that it was with difficulty that they could be seen The forces involved were utterly insignificant His dynamo was worthless as a machine Who could then have imagined that these feeble impulses would some day be pumped through wires to light large cities, and to move heavy cars loaded down with passengers? Who could have then believed that articulate speech would ever be transmitted by them? Who could then have believed that ships on the ocean would some day be in constant communication with the land, by means of such impulses transmitted through space, and that a ship in distress would thus be able to call for help? Had any prophet foretold all of this at that time, it would have been called the idle fancy of a foolish brain And yet all of these great things followed directly from those simple experiments

And the end is not yet We are beginning to see the importance of saving our fuel We may be able to grow trees, but we can not grow coal An age of water power is before us when vast amounts of power will be thus obtained, and transmitted, by these methods devised by Faraday, to distant cities Millions upon millions of dollars are now invested, and vast armies of men are employed in enterprises which followed directly from these simple experiments

When Helmholtz visited London in 1853 he wrote to his wife an account of his visit to Faraday, in which he says

Those were splendid moments He is as simple, charming and unaffected as a child, I have never seen a man with such winning ways He was, moreover, extremely kind, and showed me all there was to see That indeed was little enough—for a few wires and some old bits of wood and iron seem to serve him for the greatest discoveries

It is often said that work of such character is not for all, that only a few of the elect are capable of doing it In a sense this is true There are comparatively few who will in their younger days submit to the agonizing struggle through which one must go, in order that he may gain control of his mental faculties If he is mentally slow in his sense perception, it will be necessary for him to engage, persistently, for hours, days and years, in a mental struggle with problems which tax his utmost powers It is in this way that one finally acquires the capacity for careful and logical and persistent thinking. It goes without saying that there are comparatively few who will submit to such an

initiation. Certainly the average man is not and never has been of that class Such men are thinking men In their younger days most men are disposed to criticize the work of others Among men of science this is much less common than it was thirty or forty years ago Every one who has ever accomplished anything will recognize the truth of Goethe's remark

> It is easier to recognize error than to find truth That lies upon the surface so that it is easily dealt with, this rests in the depths, to search for which is not every man's affair

As one's powers develop and he begins to attack constructive work, and to make mistakes, he begins to take less interest in searching for errors in the work of others To search for truth is any man's affair who chooses to do so And history tells us in no uncertain way that human development has always resulted from the efforts of those who have expended most of their energy in independent thinking Sometimes the world has followed slowly. Sometimes the results have only become apparent in succeeding generations. Our industrial development has, however, always followed in the pathways marked out by scientific men Their work has always preceded the work of the engineer and the inventor And in the words of my text, When any nation has reached such a stage in its existence, that scientific discovery is put into the background as of no practical value, and the entire current of work is expended in engineering and business activity, that nation is on the way to the civilization of China.

As a nation we have before us problems that are vastly greater than any which have been solved in the past. We may assume that the future will take care of itself We may assume that our leaders in thought and in knowledge will always be with us. We should, however, remember, that there have been former civilizations in other lands, of which no trace can now be obtained, without digging below the surface of the earth.

The question which should now interest us is, whether or not our civilization is to have such an ending

It is only a century ago since one of my ancestors moved with his family from Vermont to the far west There were few roads amid the immense forests through which they wandered, and in the midst of which the family finally found a home in central New York. I personally knew, and still remember the names of some of the men who developed that country What they did was to chop down forests and burn them. What they then did should now be called by another name

There are now among us men who are ambitious to waste the resources of the country, on the plea that they are developing those resources They protest strongly against the importation of lumber from Canada, because it would interfere with the chopping down of our own trees Fifty years ago there was not a locomotive engine in the country which was operated by coal fires They were all operated by wood fires The locomotive of to-day could not be operated by wood fires, and the wood is no longer available. Then a 100-ton locomotive would have been considered an impossibility The bridges of that day would not have sustained them. At that time a 30-ton locomotive was in general use Now we have locomotives which approach 300 tons. Thirty years ago the idea that 1,000 horse-power engines would be used for developing power to be distributed by electrical means was ridiculed as absurd by electrical authorities.

Even if we take the most liberal estimate of the amount of available coal yet unburned, and consider the enormous in-

crease in its consumption, we must still admit that the burning of coal is a mere incident in human history It seems to me that it is the duty of thinking people to begin to think about such things Why should they be left to those who are continually planning to perfect and legalize schemes of public robbery? The people of the country are waiting for leaders, who have been trained in methods of careful and logical thinking, who not only are not for sale, but who can not be bought and who are not afraid

There are other duties which are demanded of thinking men It is evident that the honest public needs light on many questions which are of vital interest to all. It is possible to fool nearly half of the people, nearly all of the time For example, there are many well-meaning people to whom it would never occur that the citizens of Missouri need protection against Iowa, or Arkansas, who can be made to believe that the people of the United States need protection against Canada, or Germany or England.

What we do need protection against, first of all, is organized systems of bribery and public robbery

I know of men who have given attention to such public matters, who have engaged in a successful private business, and who among a wholly different class of men are regarded as authorities in some branch of scholarly or scientific work The man who has scholarly tastes, the man who appreciates the value of those things which money can not buy, is not likely to be dominated by the insane greed which seems to have taken possession of such a large class of our citizens. He may appreciate the approval and gratitude of those whom he has helped, and to whom his life has been an inspiration. He is not dominated by a desire to attract attention Certainly he will not seek to attract attention by spectacular or ostentatious waste of ill-gotten gains.

Perhaps we should not be far from the truth if we lay down as a fundamental axiom, that men's lives are guided by a desire to secure personal enjoyment or pleasure The differences between men arise when we observe from their behavior, what it is that gives pleasure to them. Some will undergo hardships and distress, for the joy of attaining a worthy end Some will spend their earnings for the pleasure of a midnight carouse The searcher for the unknown in nature will spend years of labor and mental toil, in the hope that he may feel the joy of finally adding his mite to the store of knowledge which his predecessors have given to the world Such work as this is often attended with a feeling which might properly be called mental distress

In the twenty-fourth series of his "Experimental Researches" Faraday describes many tedious and intricate experiments in which he sought to discover some relation between electrical action and gravitation As his biographer tells us, "He labored with characteristic energy for days, on the clock-tower of the Houses of Parliament and in the shot-tower of Southward, raising and lowering heavy weights connected with wire coils" Many times his results appeared for a time to furnish conclusive proof of his assumption. Then came a period of self criticism, and of doubt, and when the final end was reached, there remained absolutely no result As Faraday described his mental condition, "Occasionally, and frequently, the exercise of the judgment ought to end in absolute reservation We are not infallible, and so we ought to be cautious." On another occasion he said:

The world little knows how many of the thoughts and theories which have passed through the mind of the scientific investigator, have been crushed in silence and secrecy by his own severe criticism and adverse examination, that in the most successful instances, not a tenth of the suggestions, the hopes, the wishes, the preliminary conclusions have been realized

It is a matter of common observation that men who have done most to widen the boundaries of human knowledge, are the ones who are most frequently in a state of doubt They are always ready to take the whole matter into consideration again when some preliminary conclusion is confronted with conflicting evidence In physics where we seek the relation between various values which are simultaneously involved in some function, as in the bending of a beam under a load, we can vary one quantity only, and find its effect on the result When this has been done with all of the variables which are concerned, the entire equation involving the simultaneous effect of all the variables can be written When we undertake to determine the effect upon a nation, of some national policy, we are never able to control conditions in two successive experiments We can not eliminate the disturbing effect of other influences or conditions which have also changed and which are of importance in determining the result But the political orator is never in doubt He speaks with as much of assurance as a lawyer, who argues a case in court

It is not the duty of a scientific man to defend what is generally believed to be the truth The mental attitude of the advocate is foreign to every instinct that the man of science should possess In Galileo's time we can well understand how the man of science should actively contend in quarrelsome debate with those who refused to look through his telescope It was enough for them to know that there were seven openings in the head, seven metals, and seven days in the week This was proof enough that there could only be seven planetary bodies The moon and the sun were perfect as they came from the hand of the creator This was proof enough that there could be no mountains and valleys on the moon, and no spots on the sun It needs no telescope to settle such questions That all bodies do not fall with the same acceleration has been already passed upon in a prior decision It is sufficient to cite that opinion, and Galileo's experiment at the tower of Pisa counts for nothing

Galileo was himself a product of an age characterized by ideas of this kind. In his day his mental attitude was perhaps needful There are times when the soil must be plowed In our time the man of science is free to go his own way in the pursuit of his work and in publishing it to the world If one feels dissatisfied with the present, he can do nothing better than to read history.

I have often felt that scientific students of our time would be greatly benefited by reading much more of history than is their custom There are some most interesting remnants of scientific history, connected with the Moorish occupation of Spain The work of Alhazen, who lived about 1100 A D would have been creditable in any age It requires great patience for one living in this age to read European history during the times of Luther and Galileo. It is, however, only in this way that we can realize what progress the world has been making

It is, however, a satisfaction to know that nations have never been driven to bloody wars in order to enforce the doctrine of universal gravitation, or Kepler's third law, or the doctrine of evolution.

We do learn that in those earlier times,

a public official who would dare to interfere with princely schemes of public robbery, would generally lose his head Now he at most loses his position Our merchant princes are not so severe as their predecessors were

The barber of the present day is not expected to do surgical work, although his sign still gives notice that accidents may happen The bloody pole with its white bandage reminds us of the days when the barber was the surgeon The family of Poisson decided for him in his youthful days that the work of a notary required greater intelligence than he possessed, and advised him to become a surgeon It was not until 1745 that the "barberous" work of the surgeon and the surgical work of the barber were, in England, eliminated by law

Not only should one study the history of the arts and sciences, but even more inspiring are the biographies of the great men of history Most of the men who have given direction to scientific thought and work have been men who came from the most humble positions in life. Occasionally we find one coming from so-called higher levels, who was not satisfied to be simply a descendant. To read an account of the work of such men, in connection with the human element which enters into a biography, often opens up a new world to a young man He may thus learn that he possesses elements which respond to such history. It is not saying too much to say that the great mass of students in college never come into contact with the great things of the learned world They do not do enough of skirmishing in the fields of learning They waste their time in trivial matters which will have little value to them in the future They perhaps never acquire the faintest knowledge of branches of learning, which, if they knew of them, would change the whole current of their lives

And in order that one may do new work it is not necessary to hunt for new fields Remember that the Crookes tube was in physical laboratories in all parts of the world for seventeen years, before any one suspected that it was an X-ray tube Rontgen was hunting for accidents of the kind, and he accidentally discovered that there were phenomena outside of the tube that demanded attention It is only needful that one shall read and think, and the work of others, which may have been published half a century ago, will suggest something to you which it never suggested to any one before, and which may occupy your attention for years

FRANCIS E NIPHER

BRITISH VITAL STATISTICS

THE British Registrar-General has issued his return relating to the births and deaths in the first quarter of the year, and to the marriages during the three months ending December last From the abstract in *The British Medical Journal* it appears that the marriage-rate during that period was equal to 16 1 per 1,000, or 0 7 per 1,000 less than the average rate for the corresponding quarter in the ten preceding years

The 223,588 births registered in England and Wales during the quarter under notice were equal to an annual rate of 24 8 per 1,000 of the estimated population, the birth-rate last quarter was 2 7 per 1,000 below the average rate for the corresponding period of the ten preceding years, and is the lowest birth-rate recorded in the first quarter of any year since the establishment of civil registration. Among the several counties the birth-rates ranged from 17 8 in Carnarvonshire, 18 5 in Sussex, 19 6 in Northamptonshire, 20.1 in Kent, and 20 6 in Dorsetshire and in Gloucestershire, to 29.1 in Nottinghamshire, 31.3 in Carmarthenshire, 31 4 in Durham, 34 5 in Glamorganshire and 35 9 in Mon-

mouthshire. In seventy-seven of the largest towns, including London, the birth-rate averaged 24.9 per 1,000, in London the rate was 23.9, while among the other towns it ranged from 14.5 in Hastings, 15.1 in Hornsey, 16.0 in Bournemouth, 16.7 in Halifax, and 18.3 in Handsworth (Staffs), to 31.5 in Merthyr Tydfil, 33.6 in St. Helens, 35.3 in Coventry, 35.9 in Swansea, and 41.8 in Rhondda.

The excess of births over deaths during the quarter was 80,447, against 83,784, 68,281, and 85,256 in the corresponding quarters of the three preceding years. From a return issued by the Board of Trade it appears that the passenger movement between the United Kingdom and places outside Europe resulted in a net balance outward of 70,973 persons. There was an outward balance of 46,076 English passengers, 1,185 Welsh, 11,473 Scottish, 4,002 Irish, and of 8,812 foreigners, while there was an inward balance of 575 British Colonial passengers.

During the three months under notice the deaths of 143,141 persons were registered, equal to an annual rate of 15.9 per 1,000, or 1.7 per 1,000 less than the average rate for the corresponding quarter in the ten preceding years. The lowest county death-rates last quarter were 13.3 in Middlesex and in Essex, 13.5 in Kent, 13.6 in Leicestershire, 13.7 in Northamptonshire, and 13.9 in Worcestershire, the highest rates were 18.2 in Herefordshire, 18.5 in Devonshire, 19.0 in Monmouthshire, 19.6 in the North Riding of Yorkshire, and 20.2 in Carmarthenshire. In seventy-seven of the largest towns the corrected death-rate averaged 16.8 per 1,000; in 136 smaller towns the rate was 15.4 per 1,000, which was also the rate in the remainder of the country. The crude death-rates in the seventy-seven towns ranged from 7.6 in King's Norton, 8.5 in Hornsey and in Handsworth (Staffs), and 10.4 in East Ham, to 19.2 in Oldham, 19.3 in Dewsbury and in Swansea, 19.4 in Liverpool, 20.0 in Sheffield, 20.7 in Coventry, and 23.1 in Middlesbrough; in London the death-rate was 15.8 per 1,000.

The 143,141 deaths from all causes last quarter included 12,535 which were referred to the principal infectious diseases, of these, 6,147 were attributed to measles, 2,631 to whooping-cough, 1,439 to diarrhœa and enteritis (among children under two years of age), 1,369 to diphtheria, 515 to scarlet fever, 421 to enteric fever, 9 to small-pox, 2 to typhus, and 2 to pyrexia of uncertain origin.

The rate of infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 115 per 1,000 or 15 per 1,000 less than the average rate in the ten preceding first quarters. Among the several counties the rates of infant mortality last quarter ranged from 88 in Sussex, 91 in Surrey, 93 in Dorsetshire, 94 in Hampshire and in Buckinghamshire, and 95 in Hertfordshire, to 130 in Cornwall, 138 in Cumberland, 144 in the North Riding of Yorkshire, 145 in Monmouthshire, and 164 in Carmarthenshire. In seventy-seven of the largest towns the rate averaged 115 per 1,000 (being equal to the rate in the country as a whole), and ranged from 57 in Hornsey, 65 in Wallasey, 79 in King's Norton and 80 in Hastings and in Great Yarmouth, to 149 in Sheffield and in Rotherham, 151 in Grimsby, 158 in Blackburn, 165 in Dewsbury and 186 in Middlesbrough.

The death-rate among persons aged 1 to 65 years was 8.7 per 1,000 of the population estimated to be living at those ages. In the seventy-seven large towns the death-rate in this age-group averaged 9.4 per 1,000, and ranged from 3.5 in King's Norton, 4.1 in Hornsey, 4.2 in Handsworth (Staffs), 5.8 in Ipswich, 6.2 in Leicester, and 6.3 in Bournemouth, to 12.2 in Oldham, 12.3 in Coventry and in Liverpool, 13.4 in Sheffield and 15.1 in Middlesbrough.

Among persons aged 65 years and upwards the rate of mortality last quarter was 104.6 per 1,000; in the seventy-seven towns the death-rate in this age-group averaged 111.9 per 1,000, the lowest rates being 69.0 in King's Norton, 76.5 in Handsworth (Staffs), 85.8 in West Bromwich and 87.0 in Norwich and in Devonport; and the highest rates, 140.0 in Swansea, 142.0 in Huddersfield, 144.2 in

Dewsbury, 155.4 in Burnley and 158.5 in Bootle.

The mean temperature of the air last quarter was above the average in most districts, the total amount of rainfall was less than the average, and, owing to the general dullness in March, there was a deficiency in the total duration of bright sunshine during the quarter.

APPROPRIATIONS FOR THE UNIVERSITY OF ILLINOIS

THE forty-seventh general assembly of the state of Illinois, which closed its regular session on June 1, by a record breaking act, has distinguished itself in the cause of state education. Former legislatures of the state had made what was considered at the time generous appropriations for the state university. The present General Assembly, however, recognized the ever-increasing needs of the state university and its great public service by appropriating for its support for the coming biennium the sum of $3,519,300. This is the largest appropriation ever made by a state legislature to a state educational institution and a million and a quarter larger than the largest appropriation ever before made to the University of Illinois.

But this is not all. The present general assembly not only recognized the immediate needs of the university and provided for them, but it had the courage to look ahead and make wise provision for the future by levying a one mill tax for its continued support. It is estimated that this tax will yield an income to the university, two years hence, of about two and one quarter million dollars a year. Thus the legislature has crowned its important work for state education by providing what is in effect a permanent annual grant equal to the income at 5 per cent. of an endowment fund of $45,000,000.

By these acts the general assembly eloquently expresses its confidence in the management of university affairs and its general approval of the able leadership and restless energy of the university's president, Dr. Edmund J. James.

The extent and nature of the work of the university for which the legislature has made appropriations will be seen from the following items:

		For the Biennium 1911-1913
For salaries and operating expenses		$1,150,000
Books for the library		50,000
Maintenance of the College of Engineering and Engineering Experiment Station (not including building)		180,000
For the College of Agriculture and Agricultural Experiment Station (not including buildings)		799,300
For Social and Political Science		50,000
Support of Law School		50,000
Support of Graduate School		100,000
Support of College of Medicine		120,000
Maintenance and equipment of Mining Engineering		55,000
Support of ceramics		30,000
For new buildings		724,000
Armory	$100,000	
Engineering building and ground	200,000	
Building for School of Commerce	125,000	
Addition to Woman's building	125,000	
For Kiln House for Ceramics	21,000	
For agricultural buildings	153,000	
For purchase of land, Agricultural Experiment Station		20,000
Other items not included above		191,000
Total		$3,519,300

In addition to the above the university will receive from the federal government and other sources funds that will bring its income to about $2,000,000 per annum for the next biennium beginning July 1, 1910.

Of the above appropriations there is one item that should be noticed particularly as it is the first appropriation ever made by the state of Illinois for the purpose specified. It is the item of $60,000 per year for the support of the College of Medicine of the university. By this act the state of Illinois takes its place among modern states in recognizing its high duty to take measures for the protection of the health of its citizens.

No account has been taken in the above items of the appropriations made for the State Laboratory of Natural History, for the State Entomologist's Office, for the State Geological Survey and the State Water Survey, whose activities are closely allied with the work of the university

B E POWELL

SCIENTIFIC NOTES AND NEWS

THE University of Gottingen has conferred the honorary degree of doctor of philosophy upon Professor Albert A Michelson, head of the department of physics at the University of Chicago, and retiring president of the American Association for the Advancement of Science

THE George Washington University has conferred the honorary degree of doctor of medicine on Dr L O Howard, chief of the Bureau of Entomology and permanent secretary of the American Association for the Advancement of Science, for "distinguished services to science in relation to preventive medicine"

CAMBRIDGE UNIVERSITY has conferred its doctorate of science on Dr George E Hale, director of the Solar Observatory of Mt Wilson, and on Dr T W Richards, of Harvard University

DR ALLEN J SMITH, dean of the Medical School of the University of Pennsylvania, received the degree of LL D at the exercises attending the opening of the Medical School Building of McGill University

SURGEON-GENERAL CHARLES F STOKES, U S. Navy, delivered the valedictory address at the commencement exercises of Jefferson Medical College, Philadelphia, on June 5 On this occasion the college conferred on him the degree of LL D and on the following day Columbia University, from which he graduated in medicine, gave him the degree of D Sc

UNDER the auspices of the president and council of the Chemical Society, the Faraday lecture was delivered in London on June 14 by Professor Theodore W. Richards, of Harvard University. At the conclusion of the lecture the Faraday medal was presented to Professor Richards

DR W M DAVIS, Sturgis-Hooper professor of geology at Harvard University, has been appointed visiting professor at Paris under the new arrangement between Harvard and the Ministry of Public Instruction

AT the annual meeting of the London Institution of Electrical Engineers, Mr. S Z de Ferranti was elected president

PROFESSOR POHL, of Prague, has been appointed director of the institute of pharmacology at Breslau in place of Professor Filehne

THERE have retired from active service Dr Rudolf Nietzki, professor of chemistry at Bâsle, Dr Louis Isely, professor of mathematics at Neuchâtel, and Dr Bernhard Tollens, associate professor of agricultural chemistry at Gottingen

PROFESSOR CHAS W HARGITT, of Syracuse University, has recently returned from a seven-months' sojourn in Europe as a part of his sabbatic year After brief visits to the laboratories at Plymouth, London University, Munich, Vienna and Paris, four months were spent at the Naples Zoological Station, occupying the Smithsonian table Several American laboratories have also been visited

PROFESSOR BURTON E LIVINGSTON, of the Johns Hopkins University, will continue his researches at the Desert Laboratory, Tucson, Ariz, during the present summer He will be assisted by Professor J S Caldwell, of the University of Nashville

MR FREDERICK G CLAPP has been investigating the geological occurrence of petroleum in the Mexican oil fields

THE first two incumbents of the Kahn traveling fellowships for American teachers are Professor John H T. McPherson, professor of history and political science in the University of Georgia, Athens, Ga, and Professor Francis Daniels, professor of romance languages in Wabash College, Crawfordsville, Ind.

ON May 29 Professor Herbert N. McCoy, of the University of Chicago, delivered the

annual lecture before the Northwestern Chapter of Sigma Xi on the subject "Radioactivity and the Nature of Matter"

ACCORDING to *Nature* a festival in memory of Richard Jefferies was held at Swindon on Saturday, June 10 Jefferies was born at Coate, near Swindon, and spent his early life in the latter place A visit to Coate Farm, the naturalist's birthplace, and an open-air concert, morris dancing, speeches and a short service in Chiseldon Church were arranged

DR EMMA WILSON DAVIDSON MOOERS, custodian of the neuropathological collection of the Harvard Medical School, whose death we announced last week, died of streptococcus septicemia and meningitis The infection was contracted by contact with a brain from a subject dying in the recent tonsilitis epidemic of Cambridge, Mass Dr Southard, who removed the brain at autopsy, escaped with merely a septic hand

ISAIAH FAWKES EVERHART, M D, naturalist and philanthropist, died at Scranton, Pa, on May 26, 1911, aged 71 years Dr Everhart was the founder and endower of the Everhart Museum of Natural History, Science and Art A bronze statue of Dr Everhart, presented by Dr B H Warren, of West Chester, has been erected in front of the museum at Scranton, and preparations were being made for its unveiling

DR. CARL BECK, president and surgeon of St Mark's Hospital and professor of surgery in the New York Post-graduate Medical School, has died at the age of fifty-four years

DR. ALEXANDER BRUCE, known for his contributions to neurology and diseases of the nervous system, has died at the age of fifty-six years.

DR. LUDWIG KERSCHNER, professor of histology and embryology at Innsbruck, has died at the age of fifty-two years

THE U. S. Civil Service Commission announces the postponement to July 5, of the examination announced to be held on May 24, to fill the position of soil bibliographer, Bureau of Soils, Department of Agriculture, at a salary of $1,400 per annum

BARON ALBERT VON ROTHSCHILD, of Vienna, has bequeathed $40,000 to establish a prize in astronomy.

Nature states that the sum of £1,000 has been placed at the disposal of the British home secretary by a colliery proprietor to form a prize for the best and safest electric lamp for use in mines, and Messrs C Rhodes and C H Merz have consented to act as judges upon the lamps submitted The competing lamps must be addressed care of Mr C Rhodes at the Home Office Testing Station, Rotherham, and must be delivered by December 31 next

THE *Journal* of the American Medical Association states that the scientific laboratories on Monte Rosa, named after the late Professor A Mosso, of Turin, will be opened for scientific research on and after July 15 There are sections devoted to physiology, botany, physics and microbacteriology, and there are nineteen posts open to research workers from the countries or institutions which contribute to the support of the institution Applications for reservation of a place must be sent to the director, Dr A Aggazzotti, Corso Raffaello 50, Turin, Italy, not later than July 1, with specifications as to the subject of research and the credentials from the government or institution

THE old mounting of the 18½ inch equatorial of the Dearborn Observatory, which has done service for nearly half a century, has just been replaced by an entirely new mounting from the firm of Warner & Swasey Observations with the new instrument were begun on June 1.

Nature states that the British Museum has acquired, at an almost nominal price, the valuable collection of specimens illustrating the religion of Polynesia, which was long in the possession of the London Mission Society Many of the specimens are unique, and it would now be quite impossible to form such a collection. Among the most remarkable objects are the great tapering idol of the national god of Raratonga, kept swathed in

blue and white matting, Tangaroa, the supreme god of Polynesia, a wooden figure with small human-like objects sprouting from his eyes, mouth and other parts of his body, typifying his creative power, and a head-dress of black feathers, which completes a mourning costume already owned by the museum

UNIVERSITY AND EDUCATIONAL NEWS

Swarthmore College has succeeded in its undertaking of raising a half million dollar endowment fund. In addition the heirs of the late Phoebe Anna Thorne, of New York, have given the sum of $200,000 to the college, making a total of $700,000 additional endowment. These increased resources will not be used to enlarge the college, but to strengthen it, to improve its present equipment, and to aid it in carrying on its work as a small college.

The gift of $100,000 in lands by James B and Benjamin N. Duke, of $50,000 for a new building by James B. Duke, and of $10,000 by B. N Duke for campus improvements, was announced at the commencement exercises of Trinity College, Durham, N C.

A gift of $20,000 to aid general research in the study of diseases, at the Yale Medical School, has been announced from Francis E. Loomis, of the class of 1864. Further gifts of $10,000, toward the endowment of the university clinic, and to the Peruvian exploration fund, for the Yale expedition under Assistant Professor Hiram Bingham, have also been announced For the exploration fund a total of about $12,000 has been pledged.

Mr. James R. Steers, '53, has made a further contribution to the Wolcott Gibbs library of chemistry at the College of the City of New York. He has endowed it with $5,000 in five per cent. bonds, the income to be used for upkeep.

McGill University has received from Lady Graham, honorary treasurer of the Dr. A. A. Browne memorial fund, the sum of $10,000, which is to be devoted to the establishment of a fellowship for the advancement of medical science.

We learn from *Nature* that the Mathematical Society and the Society of Applied Physics of Göttingen have given 100,000 Marks to a fund for the creation of an institute of mathematics in connection with the University of Gottingen. Two donations of 50,000 Marks from manufacturing houses have also been received

It is announced that a considerable addition to the laboratory of plant physiology of the Johns Hopkins University will be erected during the present summer This will include both laboratory and greenhouse space, adapted to advanced work and research

An Imperial University Congress will be held at the University of London in the summer of 1912

A new plan of studies at the Harvard Dental School will go into effect October next During the first half year the students will divide their time between chemistry and general anatomy, including dissection of the cat, embryology, organology and histology. During the second half year they will have human dissection including special work in the anatomy of the head, and they will also have at the same time physiology The courses have been entirely recast, but the concentration system of studies has been preserved The new plan has been adopted in the hope of gain from the logical sequence of the subjects.

Only the men of the college of letters and science, the school of medicine and the commerce courses will be expected to wear caps and gowns at the commencement exercises of the University of Wisconsin. Owing to the sentiment among the agricultural, law and engineering students they will not be asked to wear the cap and gown.

At the University of Michigan assistant professor R H. Curtiss, of the department of astronomy, has been made junior professor and assistant director of the observatory to take the place of Professor W. J. Hussey, during the latter's absence at La Plata University. Assistant professor S. J. Zowski, of the engineering department, has been made junior professor of mechanical engineering and Junior Professor Alfred Holmes White, of the same department, full professor of

chemical engineering Dr C H Kauffman, instructor, has been made assistant professor of botany Aubrey Tealdi, instructor, has been made assistant professor of landscape gardening, and Dr G L Jackson, instructor, has been made assistant professor of education Dr A G Ruthven, curator of the museum, has been made assistant professor of zoology

DR. J. G FITZGERALD has been appointed associate professor of bacteriology in the University of California

WILLIAM H WELKER, Ph D, has been appointed assistant professor of biological chemistry in Columbia University

M TISSOT, an assistant in the Paris Museum of Natural History, has been appointed professor of physiology in the museum

DR. WENZELL LASKA, of the Technical School at Lemberg, has been appointed professor of mathematics in the Bohemian University of Prague.

DR. ERHARD SCHMIDT, of Erlangen, has been called to the chair of mathematics at Breslau.

DISCUSSION AND CORRESPONDENCE

THE APPOINTMENT, PROMOTION AND REMOVAL OF OFFICERS OF INSTRUCTION

IN a recent paper under the above title[1] Mr Sidney Gunn makes the following references to Brown University

> Another illustration of the way the public takes removals can be found in the case of Brown University Repeated complaints have been raised of men having been cajoled, crowded or thrust out of the Brown faculty with varying degrees of suddenness and consideration In some cases the men so treated have served the university for many years without being found incompetent or even unworthy of regular promotion—something which in most institutions is regarded as establishing a claim that prevents removal on the ground of natural unfitness.

The paragraph quoted was to be sure part of the material of an argument against the contention of President Van Hise that public sentiment would always visit speedy condemnation upon a college president or corporation if the power of removal were unfairly or unjustly used. I am not inclined to disagree with this main thesis of Mr Gunn's paper, nor do I care to enter upon a discussion of the causes or conditions of removal of members of the faculty of Brown University in recent years Such discussion could serve no good purpose, and would only lead to futile controversy I do, however, deeply regret that a reference to Brown University should appear in SCIENCE from which every reader must inevitably draw the inference that the situation at Brown is typically bad with respect to the academic freedom and the tenure of office of its teachers, that the members of the Brown faculty do not enjoy a reasonable security of tenure but are liable, even after long and apparently satisfactory service, to be removed arbitrarily by the president or governing board

That its administrative body has never made an error of judgment is more than can be said, probably, of any long-established institution, but all friends of collegiate education Mr Gunn included, should be glad to know that the indictment contained in the statements and implications of Mr Gunn's paragraph referring to Brown is not justified by the policy of the university.

The permanency of tenure of office for professors is secured by the ancient charter of the university A professor can be removed only "for misdemeanor, incapacity or unfaithfulness" The president and governing boards at the present time also recognize the fact that security of tenure, in the long run, is to the university a financial asset as well as a necessary condition of continuous and contented scholarly work and the natural and appropriate reward of loyalty and of long and faithful service. It is the well understood policy of the university to construe the principle of tenure, in accordance with the spirit of the charter, as applying to those assistant and associate professors who have served many years satisfactorily.

Instructorships are considered to be tempo-

[1] SCIENCE, May 12, 1911, p 729.

rary appointments even after the salary is increased, and the promotion from an instructorship to an assistant professorship, while it carries with it encouragement and expectation of later permanence, does not immediately commit the university to a guarantee of permanent tenure This is reasonable, for, if the instructor for any reason does not fit the particular position, after a trial of a few years, no one interested in the welfare either of the university or of the instructor himself would desire that he be promoted to a professorial position Similarly if, after a few years, the assistant professor fails to fulfil the expectations which accompanied his promotion or appointment or if he apparently has reached the limit of his growth in the environment of the particular institution, no one can fairly object to his being advised, or urged if necessary, to seek elsewhere to establish his permanent professional position, provided, of course, that he is given ample time and friendly assistance to make the change

At Brown, those teachers, whether professors, associate professors or assistant professors who, as distinguished from these younger men, have served the university many years and have been encouraged to believe or allowed to suppose that their services have been satisfactory until the time is past for a reasonably fair chance of readjustment in other positions, are insured by the university's policy of tenure against being "cajoled, crowded or thrust out of the Brown faculty." Contrary to the inference which would naturally be drawn from Mr Gunn's paragraph, such service at Brown University "is regarded as establishing a claim that prevents removal on the ground of natural unfitness." The administration recognizes its responsibility in case it fails to diagnose natural unfitness in the course of the years of probational service.

In view of this recognized policy there is in the university a feeling of security of tenure and there is also an academic freedom of opinion, utterance and action which is ideal and is highly valued and appreciated by the faculty

CORRESPONDENCE WITH THE INTERNATIONAL COMMISSION ON ZOOLOGICAL NOMENCLATURE

The secretary of the International Commission on Zoological Nomenclature feels constrained to invite the attention of the members of the zoological profession to an important point in connection with the subject of correspondence

The commission is composed of fifteen members, elected by the International Congress of Zoology The duties involve a considerable amount of tedious labor All of the members give their time willingly to this work from a pure sense of duty to science and to their profession They do not ask nor do they receive one cent of remuneration for the many hours of time and work they sacrifice in order to endeavor to carry out the duties imposed upon them

At the urgent request of colleagues, additional labors have been undertaken that were not contemplated when the commission was originally formed in 1895

With the increase of duties, the correspondence has naturally grown to not inconsiderable proportions, and this additional correspondence brings with it increased labor and increased sacrifice of time

It is a pleasure to acknowledge the fact that many of the members of the profession seek to aid the commission by valuable suggestions and it seems needless to state that this friendly cooperation is heartily welcomed and appreciated

Some zoologists, however, appear to overlook the history, duties and purposes of the commission, and appear to assume that one of its objects and duties is to receive and read communications couched in language which is hardly within the bounds of diplomatic usage.

As the executive officer of the commission, and assuming full personal responsibility for this action, taken without consulting the other members, the secretary desires to give public notice that he insists that the same

courtesies be extended to the commission which it is customary to extend to other judicial bodies and other international committees. Suggestions, advice and objective arguments are welcomed, but polemics of all kinds will be consigned, unconsidered and unanswered, to the waste paper basket.

This public notice is given only after receipt of a number of letters couched in terms which it is exceedingly difficult to construe as within the bounds of professional courtesy or diplomatic usage.

CH. WARDELL STILES,
Secretary

THE ZOOLOGICAL RECORD

The Zoological Record, published annually by the Zoological Society of London, is now also the zoological volume of the International Catalogue of Scientific Literature, and is prepared with the active cooperation of the United States government, through the Smithsonian Institution. In spite of this, when the volume for 1909 came to hand recently, I was called upon to pay $2.50 duty, a larger sum than ever before. I thereupon applied to the Smithsonian Institution, and was informed that the *Record* appeared to be entitled to free entry, according to item 517 on page 71 of the Aldrich-Payne Tariff Bill of 1909. Armed with this information, I took up the matter with the U. S. Treasury, and after a lengthy correspondence with the authorities in Washington, New York and St. Louis, have received a check for the amount paid. I publish these facts for the information of other subscribers. It should be added, that not only is the *Record* entitled to free entry, but all "books and publications issued for their subscribers or exchanges by scientific and literary associations or academies."

T. D. A. COCKERELL

PRIMITIVE COPPER HARDENING

TO THE EDITOR OF SCIENCE: In his notably sane address on "The Lost Arts of Chemistry,"[1] Dr. W. D. Richardson refers to the question, much mooted among archeologists, concerning the hardening of copper in primitive art. While his general conclusion seems just, it is nevertheless liable to be questioned by collectors of primitive artifacts in this country and perhaps elsewhere. Some personal investigation of primitive copper artifacts indicates that for two reasons these are sometimes harder than is ordinarily attained by modern artisans. (1) While ordinary copper artifacts exhumed from mounds and other burial places are commonly coated with the green oxide, the edges of knives and sometimes other portions are patinated, and usually the patina (which may extend on both sides of the blade quite to its edge) is decidedly harder, albeit more brittle, than the unchanged copper. Not infrequently this patina is mistaken for the normal condition of the metal, and the collector regards his artifact as an evidence of artificial hardening beyond the reach of modern artisans. (2) Judging both from the condition of the prehistoric artifacts and from the methods pursued by primitive artisans, the copper implements of the American aborigines were commonly hardened by hammering, albeit rather adventitiously than intentionally. Now, in the process of working, the tools employed (corresponding to hammer and anvil) were not of steel or other resilient metal, but of stone, and experiment indicates that under the blows of an inelastic stone hammer on a thin blade resting on an inelastic stone anvil, the successive impacts are not so well distributed throughout the mass of the metal as are those produced by resilient steel tools, so that the blade undergoes a sort of skin-hardening, naturally culminating in the cutting edge. Of course this effect might easily be imitated by a modern artisan using primitive tools, yet it is a factor to be reckoned with in considering the widespread belief in the superior hardness of primitive copper artifacts. Speaking broadly, the notion of lost arts, which Dr. Richardson effectively combats, is a mischievous one. Of course throughout the long, devious and vacillating course of human progress, arts have disappeared—usually because replaced by superior arts. The indus-

[1] SCIENCE, Vol. XXXIII., 1911, p. 513 et seq.

trial arts especially rank among the most permanent, not to say eternal, of all the manifestations of humanity. It is hardly too much to say that only by the extinction of entire peoples are useful arts ever lost (except as superseded by more useful devices), and until well within the period of writing any arts possibly lost by extinction of peoples left little trace.

SCIENTIFIC BOOKS

Light and the Behavior of Organisms. By S. O. Mast. New York, John Wiley and Sons. 1911.

While the present volume deals primarily with the question of the orientation of organisms the author tells us that it "may be considered a treatise on the behavior of organisms in their reactions to light." The first three chapters constituting Part I. are devoted to the historical setting of the subject and the statement of general problems and view-points. Part II. is concerned with the way in which organisms turn towards or from a source of stimulation. In addition to giving a very good résumé of the observations of others upon orientation this part contains a considerable amount of new material from the author's own researches. These include investigations of orientation in Indian corn, *Nasturtium, Amœba, Euglena* and a few other flagellates, the swarm spores of *Œdogonium, Hydra, Eudendrium* and some worms and insect larvæ. In general this work gives evidence of having been done with care and accuracy and adds materially to our knowledge of the general *modus operandi* of orientation. It is evident now to every one who has followed the work in this subject during the past few years that orientation is accomplished by a great variety of methods in different organisms. There is no such thing as a general scheme of orientation.

Loeb's theory of orientation is the author's favorite object of attack and he recurs to this doctrine and certain other views of Loeb with the persistence of Cato in urging the destruction of Carthage. It is not difficult to adduce cases that do not fall under Loeb's explanation of the way in which animals become oriented, but some of Mast's own investigations seem to afford about as good support as has been furnished for the theory which he so persistently attacks. No clearer case of orientation through the local response of the part directly stimulated could well be imagined than the one afforded by *Amœba,* and the author admits that the "method of orientation is in harmony with much in Verworn's theory and also with the essentials in Loeb's." But he adds that "it does not, however, support the idea connected with these theories, that a constant intensity produces a constant directive stimulation." I am not sure that I understand the pertinency of the criticism, for there is nothing in the theories of either of these writers which implies that the actual stimulating effect of any directive agency is subject to no variation. Both of these writers have adduced several cases which show that such variation occurs, and it is out of the question to suppose that either of them has overlooked the obvious importance of internal changes in determining the way in which an animal responds.

The author's experiments on the larvæ of *Arenicola* are of especial interest in regard to the problem of orientation. There is no reference either in the text or in the bibliography to the previous work of Lillie on the method of orientation in this form, although there is a quotation from a paper by Lillie dealing with certain features of its structure and development. The observations of Lillie are in general confirmed, but Mast has performed several additional experiments which bring out more clearly the fact that orientation is "due to difference of intensity on opposite sides" of the organism. The orienting response is shown to be due to light falling upon the eyes, the other parts of the body being apparently insensitive to this stimulus. When the larva is suddenly illuminated on one side there are no random or trial movements, but the head is bent directly toward the source of light. All the evidence points to the conclusion that orientation is the result of comparatively

simple reflex responses The question remains open whether the stimulus is produced by the direct action of light on the sensitive surface of the animal or by changes in intensity of the stimulus caused by the lateral movements of the body The question in this as in many other cases is difficult to decide Analogy with the method of orientation in *Euglena* leads the author to incline toward the latter alternative, but the experimental data obtained did not enable him to solve the problem. In either case orientation in this form is apparently as automatically regulated an activity as one might expect according to the well-known theory of Loeb

The problem of whether the rays of light *per se* or variations of light intensity *per se* afford the stimuli which cause orientation is discussed in connection with accounts of experiments on the blow fly, earth-worms and other forms There is much to be said for the efficiency of both these factors in special cases There are instances in which the shock of transition from one light intensity to another causes a marked reaction Light in other cases has a constant stimulating effect apart from any shock of transition In an organism going towards or away from the light deviations from the direct course produce a change of intensity of light falling on its two sides, that the animal turns directly and automatically into line does not of itself enable one to decide whether it turns because it is more strongly stimulated on the one side than on the other, or whether it turns on account of a change of light intensity There have been few attacks upon this particular problem and the author does well to bring it into more prominence than it has usually been accorded

Part III, entitled General Considerations on Reactions to Light, deals chiefly with the various methods of forming groups in regions of certain optimum illumination, reactions which involve no directive effect of light, and the factors which induce changes in the phototactic response. There is no discussion of any theoretical attempt to explain the reversal of phototaxis and the author advances no views of his own.

Part IV deals with reactions to light of different wave-lengths Much work in this field has given inconclusive results on account of failures to obtain pure monochromatic light and on account of not taking into consideration differences in energy of different wave-lengths While in general the rays toward the violet end of the spectrum are more potent in producing the heliotropic response in both plants and animals, the rule is not without exceptions in both kingdoms As the writer states, this is probably due to the fact that some chemical processes are accelerated by light of certain wave-length, while other chemical processes are accelerated most by light of a different wave-length Sometimes monochromatic light is more potent than white light, a fact which suggests that certain rays tend to inhibit or reverse chemical reactions which are caused by rays of a different wave-length Mast's treatment of the effect of light of different wave-lengths can not fail to be very helpful to all workers in this rather difficult subject

The final chapter on Theoretical Considerations contains, besides a general summary of results, a renewed attack upon Loeb, a short consideration of the much-refuted vitalism of Driesch, and an exposition of the general position of Jennings to which the author is a very close adherent. After stating that according to Jennings's views the reactions of an organism are fundamentally purposeful and that they depend upon previous activity as well as present external conditions, the author expounds the position of Jennings as follows "Reactions are defined as changes in the activity of organisms Such changes may occur under constant external conditions They are therefore due primarily to internal changes External factors cause reactions not directly, but indirectly, by altering internal processes (physiological states). Variability in reaction to given external conditions is due to changes in physiological states If an organism responds to light of a given intensity in a given way now, and to the same intensity in another way later, it is because the physiological state of the organism has changed" Fol-

lowing this with a statement of the principle of association, Mast continues

> Every step in the development of the theory is supported by numerous experimental facts and all seems to fit with what is known concerning the reactions of organisms Reactions, according to the theory, are as stated above, primarily due to physiological states External agents ordinarily produce reactions through the effect they have on these states By the application of this idea all the different phenomena connected with reactions to light as summarized at the beginning of this chapter can be accounted for

All this sounds rather naive as compared with the critical exposition of the preceding part of the volume It would indeed be comforting to be able to repose with such a spirit of confidence and contentment in a general philosophy of behavior, but it is perhaps pertinent to enquire if the author has not been deceived with the delusive appearance of explanation where no real explanation has been given It is an obvious truism that external factors cause reactions by altering internal processes, else they would not be reactions at all. It is equally obvious that if changes of behavior occur where external conditions do not vary they must be due to the fact that internal conditions do vary; or, in other words, if the cause of a change is not outside of the organism it must perforce be inside of the organism Phenomena may thus be "accounted for" on the basis of varying internal states, but as it is admitted that in most cases we are entirely ignorant of what these states are we are about as much enlightened as we are by the celebrated explanation of the sleep-producing effect of opium by attributing it to a dormitive principle.

There is a useful bibliography in which the effort is made to include all the important works on reactions to light in both animals and plants, but several noteworthy contributions are not included Notwithstanding minor defects, the work of Mast will prove of great value to students of the effect of light on the behavior of organisms, and the author is to be congratulated on having made so substantial a contribution to the subject.

S. J. Holmes

A Laboratory Manual of Physical Geography By R S. Tarr and O D von Engeln. New York, The Macmillan Company 1910.

Tarr and von Engeln's "Laboratory Manual of Physical Geography" is the most practical and best organized manual that has yet appeared Prepared as an exercise and notebook, with detachable leaves, and containing within its covers a large part of the necessary equipment for work, except for topographic maps, minerals and certain simple pieces of physical apparatus, it is a hand-book and guide available for both the expert and inexpert teacher Although primarily devoted to the study of physical geography, much emphasis is made of life relations and therefore the book not only meets a present condition, but makes possible a development of the phase of geography which is beginning to be emphasized by the better secondary school teachers

Of the seventy-three exercises in the book, nine are devoted to the earth as a globe, seven to excursions, eight to minerals and rocks, five to map study, twenty-six to the physiography of the lands, two to the ocean, fourteen to the atmosphere and one each to life zones and magnetism

Thus the special emphasis is good, though it is questionable whether mineral and rock study deserves to remain in physical geography and whether the ocean is not given too little emphasis The larger life relations to the ocean, apart from the phenomena associated with ocean currents and tides, are so important and fascinating that it seems unreasonable to omit them, while space is given to minerals and to the physical phenomena of condensation Laboratory work should be devoted to topics that are not capable of being learned more easily and more effectively through demonstration, and certainly condensation can not be included in this class.

The order of treatment under the land forms is original in that types of plains are studied in relation to drainage and not following drainage, and thus a better unity is preserved. Mountains are grouped according to

origin and presented in a similar all-round way The later exercises under this head are listed according to their distribution in the United States and not primarily according to the class to which they belong

Taken as a whole, however, the volume has few elements of weakness and many of strength It has been tested in practise with beginning pupils and hence is not too advanced or specialized It is a most valuable contribution to educational geography and ought to help strengthen and humanize physical geography teaching in our high schools, and it should be remembered that for many years such work has been unhuman, if not at times almost inhuman

RICHARD E DODGE

TEACHERS COLLEGE,
COLUMBIA UNIVERSITY

The Principles of Electro-deposition A laboratory guide to electro-plating By SAMUEL FIELD, A R C Sc (Lond), F C S New York, Longmans, Green & Co. 1911, 12mo Pp xv + 383

This is one of those manuals designed for the purpose of interesting further the purely technical worker, so that he may be led to learn something at least of the principles upon which the operations he observes daily are based

After considering the apparatus for the production, regulation, and measurement of the electric current, plating with copper, nickel, iron, tin, zinc, silver, gold and brass are taken up in detail, from the theoretical as well as the practical viewpoint, the methods of preparing the object for plating, as well as the finishing, after that process is complete, also being considered. This is followed by several chapters on the methods for the qualitative and quantitative analysis of the substances employed in the various processes

Whether the worker will actually gain the knowledge which the author hopes he may is a question, for much depends upon the elementary knowledge which can be assumed to be in the possession of the reader. One thing is quite certain, however,—the readers, or at least some of them, will find their interest greatly aroused by a perusal of this book, even though it may not be thoroughly understood, with the result that they may be led to seek some school where a thorough training in the subject may be acquired Books of this type are of the greatest value, for it is to them that we must look for the first step in that great advance in industrial work – the perfect combination of theory and practise

J L R M

SCIENTIFIC JOURNALS AND ARTICLES

ANNOUNCEMENT is made of the establishment of *The Journal of the Washington Academy of Sciences* It is to be a semi-monthly publication and will be sent to subscribers on the first and fifteenth of each month, or during the summer may appear on the fifteenth only, as double numbers The first number will be issued about July 15, but after 1911 the volumes will correspond to the calendar year The present *Proceedings of the Washington Academy of Sciences* will be discontinued after the completion of the current volume The *Journal* will be a medium for the publication of original papers and a record of scientific work in Washington It will accept for publication (1) brief papers written or communicated by resident or non-resident members of the academy, (2) abstracts of current scientific literature published in or emanating from Washington; (3) proceedings and programs of the affiliated societies, and (4) notes of events connected with the scientific life of Washington The editors are George K Burgess, Bureau of Standards, Barton W Evermann, Bureau of Fisheries, and Frederick Leslie Ransome, Geological Survey Illustrations will be used only when necessary, and will be confined to text figures or diagrams of simple character The editors, at their discretion may call upon an author to defray the cost of his illustrations, although no charge will be made for printing from a suitable cut supplied with the copy.

THE contents of the *Astrophysical Journal* for June are as follows:

"On Doppler's Principle in Connection with the Study of the Radial Velocities on the Sun," A. Cotton.

"On the Magnetic Separation of the Spectral Lines of Calcium and Strontium," B. E. Moore.

"On the Radiation of the Companion of Algol," Joel Stebbins.

"On Regularities in the Spectrum of Neon," Herbert Edmeston Watson.

"Application of the Interference Method to the Study of Nebulæ," Ch. Fabry and H. Buisson.

"Observations of Nova Lacertæ at the Yerkes Observatory," Edwin B. Frost.

"Photographic Determinations of Stellar Parallax made with the Yerkes Refractor." VI, Frank Schlesinger.

The June issue of the *Journal of Comparative Neurology* contains the following articles:

"The Evolution of the Sympathetic Nervous System in Vertebrates," Albert Kuntz.

"The Olfactory Nerve and the Nervous Terminalis of Ameiurus," Charles Brookover and Theron S. Jackson.

"The Nervus Terminalis in Urodele Amphibia," Paul S. McKibben.

"Localization of the Motor Area in the Sheep's Brain by the Histological Method," Jessie L. King.

PRE-COLUMBIAN REFERENCES TO MAIZE IN PERSIAN LITERATURE

That maize is of American origin is no longer a disputed question, but the discussion of the possibility of its having been known in Europe and in the east before the discovery of America by Columbus is by no means closed.

There was much written on this subject in the first quarter of the nineteenth century, and one of the historical references to which much importance was attached is an alleged mention of *rous* by Mirkhond, a Persian historian of the fifteenth century (1433–1498). The authority for the existence of such mention by Mirkhond is Herbelot, an orientalist of note, who uses the word *rous* as synonymous with *blé de Turquie*, which was a name for maize in common use at the time.[1]

Under the word Rous, in the "Bibliothèque orientale," Herbelot says (italics ours). "Rous. Name of the eighth son of Japhet, son of Noah, from whom Russia, which we now call Muscovy, has taken its name. Mirkhond wrote in the genealogy which he has given us of the Mogols, ancestors of Jenghiz Khan, that Rous was of a very different disposition from his brother Khozar . . . so that Khozar was obliged, in order to live in peace with his brother to yield to him all the islands of this great river (Volga) which empties into the Sea of Khozar which we call Caspian. Rous sowed in all these islands the wheat which we call *de Turquie* and which the Turks still call, to-day, in their language, by the name of *rous* and boulgar."[2]

Bonafous, in his monumental work on maize quotes the above and says (italics ours). "The celebrated orientalist, Herbelot, refers to a passage from Mirkhond, a Persian historian of the fifteenth century of which the translation, *if it is exact, would leave no doubt that maize was known in the Old World before the discovery of the New*."[3] Bonafous proceeds to say, however, that after an examination of the text of Mirkhond, at the place

[1] Harshberger, "Maize: A Botanical and Economic Study," University of Pennsylvania, Contributions from the Botanical Laboratory, Vol. 1, p. 89, Browne, "Maize or Indian Corn," American Institute, Annual Report, Vol. 5, 1847, p. 412.

[2] "Rous. Nom du huitième fils de Japhet, fils de Noé, duquel la Russie, que nous appellons aujourd'hui Moscovie, a pris son nom. Mirkhond écrit, dans la généalogie qu'il nous a donnée des Mogols, ancêtres de Ginghizkhan, que Rous étoit d'une humeur bien opposée à celle de son frère Khozar, . . . en sorte que Khozar fut obligé, pour vivre en paix avec son frère, de lui céder toutes les isles de ce grand fleuve qui se décharge dans la mer de Khozar, que nous appellons Caspienne. Rous fit semer dans toutes ces isles *le bled* que nous appellons *de Turquie*, et que les Turcs appellent encore aujourd'huy en leur langue du nom de *rous* & boulgar." (Herbelot, "Bibliothèque orientale," 1777–78, Vol. 3, p. 137.)

[3] "Le célèbre orientaliste d'Herbelot rapporte un passage de Mirkhond, historien persan du quinzième siècle, dont la version, *si elle est exacte, ne laisserait pas douter que le maïs n'était connu dans l'Ancien-monde avant la découverte du Nouveau*." (Bonafous, "Histoire naturelle du Maïs," 1836, p. 22.)

indicated by Herbelot, he finds nothing to justify the latter's statement in regard to *rous*, and adds, as he dismisses the subject, "Either this author must have drawn from some other source than that which he indicates, or a strange confusion must have prevailed among the notes which he had collected"[4]

This judgment of Bonafous' seems for the time to have closed the question, but the investigation of the subject of the origin of maize in connection with some bibliographical work being done in the Bureau of Plant Industry, of the United States Department of Agriculture, has revealed the fact that several scholars of note agree that Herbelot and others often ascribed to Mirkhond statements which were really taken from the writings of Khondemir[5] (1475–1534)[6]

Khondemir wrote at almost the same time as Mirkhond, although he was his grandson,[7] and his best known work, the Khelassé-al-âkhbar, is very nearly identical in subject matter with Mirkhond's History of the world, the Rauzet-al-safa Reinaud says "The Khelassé-al-âkhbar which, however, is for the most part only an abridgment of the Rauzet-al-safa, composed by Mirkhond, has furnished Herbelot with a large part of his historic articles"[8]

[4] "Ou cet auteur aura puisé à une autre source que celle qu'il indique, ou une étrange confusion se sera mise dans les notes qu'il avait rassemblées" (*loc. cit*)

[5] Variously spelled, Khondemir, Khwand amir, Chuandamir

[6] Silvestre de Sacy, "Mémoires sur diverses antiquités de la Perse," p xiii, Langlès, in "Notices et extraits des manuscrits de la Bibliothèque nationale," Vol 5, 1799, p 193, Audiffret, in Michaud, "Biographie universelle," Vol 29, 1821, p 133

[7] Khondemir is often spoken of as the son of Mirkhond, but he himself says that Mirkhond was his maternal grandfather (Rieu, "Catalogue of the Persian Mss in the British Museum," 1879, Vol. 1, p. 96.)

[8] "Le Khelassé-al-âkhbar . . . qui, du reste, n'est le plus souvent qu'un abrégé du Rauzet-al-safa, composé par Mirkhond, a fourni à d'Herbelot une grande partie de ses articles historiques." (Reinaud, in Michaud, "Biographie universelle," Vol 22, 1818, p 378)

The similarity of subject matter in the two works is shown by a comparison of the summaries of the two parts in which we are especially interested—part 9, of the Khelassé-al-âkhbar, and part 5, of the Rauzet-al-safa Of the former Reinaud says, "The author goes back to Japhet He undertakes to relate everything worthy of note that has happened in the northern countries of Asia, and then gives many details of the wars of Jenghiz Khan and of his descendants"[9] Of part 5, of Mirkhond's Rauzet-al-safa, Jourdain says "Introduction to the history of Jenghiz Khan, in which Mirkhond traces that of some Tartar and Mogol princes from Japhet, son of Noah, to this victorious Mogol"[10]

Having thus seen, first, that the two authors, Mirkhond and Khondemir, were often confused, and second, as a reason for the confusion, that the subject matter of the Khelassé-al-âkhbar of Khondemir and the Rauzet-al-safa of Mirkhond is, for the most part, the same, it seems reasonable to advance the conjecture that Herbelot drew his information from Khondemir rather than from Mirkhond, and that this probable error in crediting the quotation accounts for the failure of Bonafous to verify the reference

The statement concerning maize ascribed to Mirkhond loses none of its value in the investigation of the early history of maize, if taken from the writings of Khondemir, so that an examination of his writings, especially part 9, of the Khelassé-al-âkhbar, becomes important A copy of this work is in the

[9] "L'auteur remonte jusqu'à Japhet Il s'attache à relever tout ce qui s'est passé de remarquable dans les contrées septentrionales de l'Asie, et fournit ensuite beaucoup de détails sur les guerres de Djenguyz khan et de ses descendants" (Reinaud, in Michaud, "Biographie universelle," Vol 22, 1818, p 379.)

TERRESTRIAL MAGNETISM

THE results of magnetic observations made by the Coast and Geodetic Survey between July 1, 1909, and June 30, 1910, have recently been printed at the Government Printing Office in Washington The report is edited by R L Faris, Inspector of Magnetic Work, assistant, Coast and Geodetic Survey The report includes the values of the three magnetic elements as measured during the fiscal year, at two hundred and thirty-two stations on land distributed through thirty-nine states and territories Several other land stations were occupied and partial results are given for these Of this number, seventy-five were "repeat" stations, nearly one third of the whole number "The resulting values of annual change show that, as compared with 1905, west declination is increasing more rapidly in New England and the Middle States and east declination is increasing more rapidly in the western part of the country. The position of the line of no change is apparently about the same as in 1905" The year 1905 is doubtless referred to because to that year the last and most complete declination charts yet printed for the entire country were uniformly reduced. The results of a considerable number of observations at sea are given in this report In connection with the land work, the continuous records of the magnetic observatories, five in number, were available, except for the time during which the instruments of the observatory at Baldwin, Kans, were being removed to Tucson, Ariz, the observatory at the former place being discontinued in October, 1909, and a new one established at the latter in November, 1909. SPECIAL ARTICLES

REDISCOVERY OF SOME CONRAD FORMS

T A CONRAD in "Description of Cretaceous and Tertiary Fossils," published in part two of the Report on the United States and Mexican Boundary Survey, describes and figures the following cretaceous forms collected by Arthur Schott, ascribing them to the localities given

Mactra texana,	Prairie between Laredo and Rio Grande City
Cardium congestum,	Devils River
Rostellaria? collina,	Between Devils River and the Pecos.
Rostellaria? texana,	
Natica collina,	
Natica texana,	
Buccinopsis parryi,	

The first-named locality is in the Eocene and at the others only rocks of Fredericksburg and Washita are exposed These forms have not since been found in either locality named and I have not been able to find any record of their having been recognized, since the time of their description, anywhere else in this region, although, as will be shown later, one or two of them have been collected by other workers in this field

In working over the collections made in January, 1909, by Messrs W. F Cummins and W Kennedy along the Rio Grande below Eagle Pass, I found a number of fairly good specimens of each of the species named

Our localities and collections are as follows

Mouth of Cuevas Creek·
Rostellaria? (*Volutomorpha*) *texana* Con.
Cardium congestum Con

One and one half miles above Las Isletas:
Mactra texana Con.
Pholadomya sp.
Buccinopsis parryi Con.
Rostellaria? (*Volutomorpha*) *texana* Con.
Etc.

Wash 1 m above Las Isletas·
Sphenodiscus pleurisepta Con.
Ostrea cortex Con.
Mactra texana Con.

Pholadomya sp
Cardium congestum Con
Buccinopsis parryi Con
Rostellaria? (*Volutomorpha*) *texana* Con
Pugnellus sp Etc

Las Isletas
Sphenodiscus pleurisepta Con
Mactra texana Con
Cardium congestum Con
Turritella sp Etc

Arroyo Toro Colorado, 1 m below Las Isletas
Sphenodiscus pleurisepta Con
Nautilus dekayi?
Ostrea sp
Mactra texana Con
Crassatella sp
Cardium congestum
Breviarca sp
Buccinopsis parryi Con
Pugnellus sp
Natica collina Con
Natica texana Con
Rostellaria? (*Volutomorpha*) *texana* Con
Etc

This locality also furnishes a number of specimens of crabs

A selection of specimens representing several of the species under discussion, together with a number of others occurring in the same beds, were submitted to Dr T W Stanton, of the United States National Museum, and my identifications of the Conrad forms were confirmed by Dr L W Stephenson, who states that the *Rostellaria?* of Conrad is a Volutomorpha

Major Emory, in the first part of the Boundary Survey report, on page 68, gives a description of Las Isletas and the falls of the Rio Grande with a full-page illustration opposite This description would indicate that the falls of the Rio Grande and Las Isletas were the same The truth is that Las Isletas is located about the mouth of Castaño Creek, while the falls are some four miles lower down the river just below the mouth of Caballero Creek

It will thus be seen that our collections were made from localities directly on the line of travel of the Boundary Survey party and it seems highly probable that the original specimens described by Mr Conrad were in reality obtained from these same beds

The horizon is the uppermost portion of our Escondido beds The fossils are among the latest Cretaceous forms of which we have any present knowledge in this region

The Cretaceous-Eocene contact is well shown three miles below Toro Colorado, just above the falls of the Rio Grande and on Caballero Creek

The only other records I can find of any of these forms are as follows

Professor G D Harris, in "The Tertiary Geology of Southern Arkansas," gives a list of fossils collected by Dr C A White in 1887 at his camp eighteen miles southeast of Eagle Pass, Texas, which were supposed to be basal Tertiary Among these there is a cardium which Mr Harris figures both in this paper and later with his Midway fauna "Bulletin of American Paleontology, No 4," without giving it a specific name

This camp was probably at the Eagle Pass-Laredo road crossing near the junction of Cuevas and Peña creeks and on or near the Cretaceous-Tertiary contact The cardium is unquestionably the *Cardium congestum* of Conrad, while the other forms named by Professor Harris are from the overlying Midway.

Mr T W Vaughan in his Report on the Rio Grande Coal Fields of Texas gives a list of fossils collected 18½ miles southeast of Eagle Pass This must also have been in the same vicinity His list contains a form identified as "*Mactra* cf *mooreana*" which, in view of our later discovery, may be more properly called *Mactra texana*, and *Cardium* cf *eufalense* may be *Cardium congestum*.

E. T DUMBLE

BACTERIOLOGICAL METHODS FOR THE ESTIMATION OF SOIL ACIDITY

THE general prevalence of acidity in the older soils of the United States has been the cause of increasing comment, within the past few years. It is well known that the tendency of cultivated soils to become acid is intensified by the use of commercial fertilizers, and, gen-

erally, by the more intensive methods in vogue in portions of the eastern states. Since profitable cropping becomes impossible in soils that are strongly acid, the liming of soils is now receiving a good deal of attention. The subject of lime and liming is freely discussed in the agricultural press, and the experiment stations are asked to supply farmers with detailed information as to the amounts and kinds of lime needed for different soil types, and for different systems of cropping. In view of the constantly increasing interest in lime and its application, it is desirable that reliable methods be provided for estimating the lime requirements of soils. The search for chemical methods that would supply the desired information was begun many years ago, and a considerable number of methods have been proposed as suitable for this work, unfortunately, however, agricultural chemists find themselves unable to decide on any chemical method that would give reliable results. Some years ago a method was proposed by Tacke that proved of certain value for the moor soils of Germany. More recently Süchting has attempted to improve the method by correcting certain defects in it, but even in its improved state the method leaves much to be desired, it is cumbersome and far from reliable. Similarly, methods have been proposed in the United States by Pettit and Hopkins and, also, by Veitch. These methods have been tested under different conditions, and have failed to give concordant results.

In view of the lack of a satisfactory method for the quantitative estimation of soil acidity, and in view of the evident need for a method of this character, it is eminently proper to make a careful study of new methods that seem at all promising. Among the new methods that could be suggested, for this work, the writer would include methods based on certain bacteriological reactions. It is well known that the development of bacteria in any culture medium is directly affected by the reaction of the latter. When the acidity of the medium is increased beyond a certain point, bacteriological development is retarded, or entirely stopped. For this reason, it appears evident that if to any neutral medium there be added increasing quantities of acid soil, a point will be finally reached when the acid in the soil added would preclude further development of the organisms. Following out this line of thought, the writer prepared a series of media of varying reaction. Several portions of bouillon were prepared and adjusted to the following reactions: (*a*) Neutral, (*b*) one half per cent. acid, (*c*) one per cent. acid, (*d*) one and a half per cent. acid, (*e*) two per cent. acid, (*f*) three per cent. acid.

When portions of these media were inoculated with pure cultures of *B. mycoides* or *B. subtilis*, growth occurred in the bouillon containing up to two per cent. of acid; beyond that the growth was very slight. When similar portions of bouillon had added to them one half gram, one gram, three grams, five grams and ten grams of soil, respectively, growth occurred in the different tubes depending on the amount of acid present in the medium, or that supplied by the soil. If, previous to the addition of the soil, the latter was mixed with ten per cent. of its own weight of calcium carbonate, growth occurred in all of the tubes, even those that had contained bouillon with three per cent. of acid.

These preliminary experiments demonstrated, therefore, that the amount of acid present in cultivated soils may be determined quite accurately by comparing bouillon of varying reactions with equivalent quantities of neutral bouillon containing varying amounts of soil. The proposed method may be utilized in still another direction, in that varying quantities of soil be added to measured amounts of bouillon, and, after sterilization, the bouillon be inoculated with a standard culture of ammonifying bacteria. At the expiration of a certain length of time the ammonia formed could be distilled off, and determined in the usual way. Since the acid added by the varying quantities of soil would affect the development of the organisms to an unequal extent, the amounts of ammonia formed might be used as a fairly accurate measure of the retarding effect of the acid present in the soils. The quantitative rela-

tions may be established by comparing bouillon thus provided with varying amounts of soil with equivalent portions of bouillon, to which varying amounts of standard acid had been added.

Instead of employing ammonifying bacteria for estimating the acid present in soil samples, nitrogen-fixing species of the *Azotobacter* group could be used. It is well known that *Azotobacter* will grow by preference in neutral or slightly alkaline media, hence, mannite solutions could be made up and portions of it treated with varying amounts of soil as described above. After sterilization and cooling, the several portions could be inoculated from some pure culture of *Azotobacter*. At the end of a given length of time, the total nitrogen present could be determined and the amounts fixed used as a guide in measuring the retarding effect of the acid present in the soil sample. In the same way, nitrifying or other bacteria could be utilized for the quantitative estimation of soil acidity. It is expected that the data accumulated by us will be available for publication at an early date.

JACOB G. LIPMAN

RUTGERS COLLEGE,
NEW BRUNSWICK, N. J.

AN INTERESTING OLD WEAVING TECHNIC

ON a recent expedition of the American Museum to the Pima-speaking tribes of southern Arizona there was found the remnant of an old technic in basket-work which has almost entirely disappeared from this people.

It is a crude wrapping of a pliable binding element over stiff slats which are arranged in parallels—a wrapped weaving and found with three variations.

It appears on a few old house doors, shelves, cradles and cages in the out-of-the-way villages where the people have still preserved the early mode of construction and it seems the simplest way of uniting stiff slat-like strips by means of a soft pliable binding element.

This binding element was formerly of thong or native string—both occasionally met with now—but more recently it is of white man's rope, strips of cloth or even wire. The slats are generally the smooth, light ribs of the giant cactus Saguara. These are placed in a parallel series, while in the simplest forms of wrapping the binding element passes forward over two slats on the outside, backward over one on the inside and then repeats the process, thus forming a simple wrapped weaving. When greater strength is needed an extra slat is placed perpendicularly across the parallel series and bound to them by each wrap of the binding element, which in more frequent varieties gives an extra turn about each slat. This last technic is known as lattice wrapped weaving.

The possible evolution of the last crude basket technic from the simple process of the tying of twigs and fibers in their latticed house construction is interesting, as well as a similar development of the wrapped weaving from the plain bindings on one type of their cradles.

Indeed the thought suggests itself, might it not be possible that this crude wrapped weaving, because of its great simplicity, was one of the earliest to develop, especially in regions as destitute of suitable basket material as the desert country of the Pima? May not this technic hold a place with the others which lay claim to be the earliest technics—plaiting, with its over and under passing strips, wicker, with its interlacing twigs, wattling, with its twining elements?

Lattice wrapping repeats itself among the wild tribes in a number of the Malaysian Islands in crude traps and baskets, and on the Lower Congo in more refined basket work. Could its distribution through the desert region of America during early times be more closely traced, no doubt, we would find it a frequent technic, for it appears as far south as Mexico in the wagon box of the old oxcart. A close surface of the same technic also exists to the north among the Pomo, the Nez Perce, the Makah and on some of the old Salish blankets.

AMERICAN MUSEUM,
NEW YORK

SOCIETIES AND ACADEMIES

THE HELMINTHOLOGICAL SOCIETY OF WASHINGTON

The fifth regular meeting of the society was held in the rooms of the zoological division of the Public Health and Marine Hospital Service on March 14, 1911, Dr Stiles acting as host and Dr Ransom as chairman The following foreign corresponding members were elected Raphael Blanchard, Max Braun, Otto Fuhrmann, I Ijima, L A Jagerskiold, S J Johnston, Robert T Leiper, Otto von Linstow, Arthur Looss, Max Luehe, Sir Patrick Manson, Francesco Monticelli, L G Neumann, George H F Nuttall, Corrado Parona, Edoardo Perroncito, Theodor Pintner, Alcide Railliet, Arthur E Shipley and Fritz Zschokke.

Dr. Garrison gave a summary of a report by Surgeon C S Butler, U S Navy, and himself upon the parasites found at autopsy upon dogs, cats and rats at the U S Medical School during the past year Twelve dogs, ten cats and ten rats (*Mus documanus*) were examined with the following results

Dogs—*Filaria* (species undetermined), two infections, *Ascaris canis*, five infections, *Trichuris depressiusculus*, one infection, *Ancylostoma caninum*, five infections, *Tænia pisiformis*, three infections, *Dipylidium caninum*, six infections

Cats—*Ascaris canis*, eight infections, *Tænia teniaeformis*, two infections, *Dipylidium caninum*, six infections

Rats—*Trypanosoma lewisi*, one infection, *Trichinella spiralis*, one infection, *Trichosoma hepaticum*, four infections, *Trichosoma crassicauda*, seven infections (two bladders not examined), *Heterakis spumosa*, eight infections, *Hymenolepis nana*, one infection (in white rat), *H diminuta*, five infections, *Cysticercus fasciolaris*, eight infections

In addition, the examination of about twenty cock roaches showed infections with *Amœba blattæ* and numerous ciliates and flagellates. No gregarines were found

Dr Stiles called attention to the desirability of using fresh material for parasite study in class work

The secretary read a short note by Mr. Crawley on *Trypanosoma americanum* This parasite has been found in dried smears of centrifuged bovine blood This is of interest, since the trypanosome has hitherto been found only in bouillon cultures of the blood. The morphology of the organism as found in the fresh blood is the same as that of specimens appearing in culture tubes.

Mr Hall presented a paper entitled "The Limitations of Fecal Examination as a Means of Determining Existing Parasitism of the Digestive Tract" Certain writers have claimed a relation between the number of parasites present in any host and the number of eggs in a given amount of fæces from that host. This does not appear to be a general truth with wide application Besides the element of chance in the detection of eggs, there are certain conditions which permit of parasitism of the digestive tract without eggs in the fæces to indicate it Some of these conditions are (1) Infections with nematodes, usually light, where only males are present, (2) recent infections, at times heavy, in which the infecting larvæ of any species have not yet reached the egg producing stage, (3) interruption of egg production, as by breaking of strobila in tapeworms, or cessation of egg production, as in the case of barren nematodes, (4) irregularity of passage of eggs from the host, due to purging, passage of mucus, diarrhœa, use of thymol or alcohol, etc Consecutive and careful examinations of the fæces of a given animal show days when eggs of various kinds are abundant and days when they are scarce or missing This would be particularly true of cestodes Negative examinations must be considered doubtful and must be checked at intervals if infection is suspected

Dr Stiles presented a paper entitled "A Comparison of New England and Southern Mills with Reference to Natural Advantages and the Presence of Parasitic Diseases"

The sixth regular meeting of the society was held in the rooms of the zoological division of the Public Health and Marine Hospital Service on April 11, 1911, Dr Stiles acting as host and Dr Garrison as chairman.

The following American corresponding members were elected F D. Barker, Cooper Curtice, C A Kofoid, E Linton, W S Nickerson, H S. Pratt, Allen J Smith, L. D Swingle, A E Verrill, H. B Ward, Creighton Wellman, D G Willets and R. T. Young

Dr Stiles presented a note on a case of poisoning by the Portuguese man-of war. The poisoning had been attributed to the fish which commonly accompanies this cœlenterate. This was an error, as the stings were due to the jellyfish itself. These stings were very painful and persisted for some time in spite of treatment. The subject of poisoning by jellyfish is one that has not received adequate study.

Dr. Stiles presented a second note on the findings in fecal examination of 82 southern school children aged six to twelve years. Infection with hookworm was found in 5 per cent, with *Ascaris* in 41 per cent, with *Trichuris* in 15 per cent and with *Hymenolepis nana* in 6 per cent.

Dr. Ransom presented a paper entitled "A New Cestode from an African Bustard" in which was described a new species and genus, belonging to the family Davaineidæ. The specimens on which the description is based were collected by Mr. Loring, of the Roosevelt African Expedition, in British East Africa, from the intestine of a bustard, *Neotis caffra*. The worms are characterized particularly by the presence of ten to twelve rows of very numerous hammer shaped hooks on the rostellum. Parauterine organs are present in gravid segments. The complete paper will appear in a forthcoming publication of the Smithsonian Institution.

Mr. Hall presented the following notes:

The Coyote as a Host of Multiceps multiceps

Curtice in 1890 first suggested that the adult gid tapeworm might occur in the coyote. In 1910 Hall noted the likelihood of this being true and pointed out that if it were true, then the most essential step in the prophylaxis of gid was the destruction of the heads of sheep dying of this disease, since the other prophylactic measure which is commonly advocated, the administration of tapeworm medicines to dogs, is obviously inadequate if coyotes also carry the parasite. In another article in the same year Hall noted that we had absolutely no evidence as to whether the coyote carried the adult worm, and that the only known host is the dog. The data regarding the blue fox and red fox as hosts of the gid tapeworm are quite inadequate and these animals must be considered doubtful hosts on the evidence at hand. There is no record of any sort as regards the wolves, martin or polecat, all of which have been noted as possible hosts.

To settle the question as to whether the coyote carried the adult gid tapeworm, a matter of considerable interest in that the coyote is the most common of the wild carnivora which prey upon western sheep, the experiment was tried of feeding the larval *Multiceps multiceps*, recovered by operation from the brain of a giddy sheep, to two coyotes. The sheep was operated on April 4, 1911, and the cœnurus was fed to the coyotes shortly after the operation, each animal receiving about half of the cyst. One coyote was found dead the morning of April 10. Post mortem examination showed death to be due to septicæmia. The entire length of the small intestine showed severe ecchymotic hemorrhage. Fifty two heads of *M. multiceps* were recovered from the intestinal contents. A comparison of these worms after six days' development with some recovered from a dog after ten days' development shows the worms had established themselves and were developing normally. They were still very small, of course, but there is no reason to suppose that they would not have developed to maturity if the coyote had lived.

The coyotes, *Canis nebracensis*, according to Dr. Bailey, of the Biological Survey, were obtained in northern Montana in the area where gid is enzootic and the coyote, therefore, must be considered, in view of the experimental findings, as sharing with the dog the responsibility for carrying the gid parasite and maintaining the gid disease in that state.

A Third Case of Multiceps serialis in the Squirrel.

In a list of occurrences claimed for the larval *Multiceps serialis*, Hall in 1910 noted that Cobbold in 1864 had recorded *M. serialis* under the name by which it is more commonly known, *Cœnurus serialis*, from an American squirrel in England, the host being specified in a later article by Cobbold in 1879 as probably *Sciurus vulpinus*, and that Cagny in 1882 had recorded a second case from the squirrel, *Sciurus vulgaris*, in France. Hall accepted these records as probably correct. It was a fair assumption that Cobbold's cœnurus would be the same species as that found in another rodent, the rabbit, rather than the species found in the sheep. He did not specify whether the American squirrel was merely an American species or the animal in question was actually from America. If it was infected in America at that date, it would be much more likely that the parasite was *M. serialis* than *M. multiceps*, as the latter form is much the more rare and limited in distribution now and probably was even more so then. Kunsemuller, in an article in 1903, thinks this cœnurus of Cobbold's was probably *M. serialis*. Cagny found his cœnurus in a squirrel which had been caught young and kept three years. His specimen was examined by Mégnin and Railliet, both of whom pronounced it *Cœnurus serialis*.

In the article already noted, Hall stated that it was to be expected that a parasite like *M. serialis*

would be rare in a host like the squirrel, as the squirrel's food is of such a nature, consisting as it does largely of nuts, that fæcal contamination by carnivorous hosts of the adult worm would only occur very rarely.

Recently the writer has produced the larval *M. serialis* in an American squirrel, *Sciurus carolinensis*, by feeding proglottids of the adult worm from the dog. This proof that the squirrel may act as host of *M. serialis* warrants us in accepting Cobbold's and Cagny's cases without reservation.

The squirrel was fed December 29, 1910, with fifteen proglottids collected eight days before from the fæces of a dog infected with the adult *M. serialis* by feeding the larval form from the rabbit. The proglottids had been kept in water from the time they were collected. Superficial examination indicated that some of the proglottids were gravid and some were not. As the proglottids were injected into the mouth the squirrel stored part of them in the cheek pouches, but it was certain that the rotten proglottids would release some of the eggs and that these would be swallowed even though the proglottids might be rejected later. Ninety-two days after ingesting the proglottids, the squirrel died. It had been active up to two or three days before death and had then remained down, clawing at its jaws occasionally. Before the skin was removed, the swellings on the abdomen, back and legs plainly showed the presence of the parasite cysts. After skinning the animal, the cysts were found on the lower abdomen, the middle of the back, the right shoulder and side, the right hind quarter, the left thigh, the left hind quarter, the left calf and the left breast, side and shoulder. An incision along the abdomen did not disclose any on the viscera. The thorax was not opened, and the specimen was preserved intact except for two cysts which fell out from a superficial position under the skin on the abdomen. One of these was cut in two and both cysts were put in the ice box at a temperature of 12 to 14° C. for 44 hours. At the end of that time they were immersed in warm water. The one which had been cut in two showed no sign of movement and was apparently dead. The other cyst, which had been punctured and lost a large part of the contained fluid, showed the contractile movements characteristic of bladder-worms and was cut in two and fed to two dogs.

The cysts showed the linear arrangement of scolices which is often found in *M. serialis* and from which the species takes its name. The identification of the parasite in this case is based less on this, however, than on the fact that it was produced by feeding the adult worm.

The secretary read a paper by Mr. Foster entitled "Some Experiments in the Development of *Tænia tæniæformis* (Bloch, 1780) Stiles and Stevenson, 1905, with an Account of Coccidiosis in the Cat." By feeding experiments the larval parasite was developed in the rat from the cat tapeworm and the cat tapeworm developed in turn from these larvæ. Attempts to infect dogs failed. Some differences were found in the larval and adult hooks. In general the results agreed with those of earlier experiments. A coccidium found in the cat proved to be much larger than *Coccidium bigeminum*, the only form hitherto reported from the cat. It resembled *Eimeria stiedæ* in size but differed from it in the piriform shape of the oocyst and the absence of residual protoplasm.

Dr. Garrison gave a demonstration of a new intestine tray for autopsies. This consists of a copper sheet 30 inches long, 10 inches wide at the broad end and 5 inches wide at the narrow end, with a raised edge an inch and a half high, and with a steel rod attached to the raised edge where it is prolonged along the broad end and running above the tray to the narrow end where the rod rests on the body of the tray, the end of the rod curving downward over the narrow end of the tray. At the ends the tray is bent down to form vertical supports 6 inches long at the wide end and 4 inches at the narrow end. The floor of the tray is convex upward, the middle being about an inch higher than the sides. In use the tray is placed over two pails or jars with a slight slope downward toward the narrow end, or else the tray is stood up in two shallow dishes, the slope being obtained by virtue of the greater length of the vertical support at the broad end.

The intestines are placed in the jar or other receptacle at the lower narrow end of the tray and one end of the intestine is pulled up on the steel rod. The section of intestine held by the rod is then cut open and falls on the floor of the tray where it can be examined and washed, the contents going into the lower jar. When one section of intestine is examined it is placed in the upper jar at the same time that a fresh section is pulled on to the rod. The size of the rods varies with the size of the animals examined. To facilitate detection of parasites the tray should be painted or enameled black. The tray can be easily cleaned and sterilized.

THE PURPOSE AND SPIRIT OF THE UNIVERSITY[1]

MODERN students of human nature have changed the old saying, "Many men, many minds," into the new dictum, "One man, many selves" There is much talk of multiple personality Our complex modern life reflects itself in a composite person A man is said to have as many selves as there are social groups of which he feels himself a member To maintain a business self which can look a moral self straight in the eye, to have a theological self on good terms with a scientific self, to keep the peace between a party self and a patriotic self, to preserve in right relations a church self and a club self—such are the present problems of many a man or woman One way to escape embarrassment is to invite at a given time only congenial and harmonious selves, and to banish from the company the selves that are discordant and disconcerting The strong soul is he who can summon all his selves into loyal team play. Personality is the name men give to this unity of the self, and purpose is the organizing principle. Only as many groups of thought and feeling are schooled into cooperation by a well-considered, steadfast aim can a man be master of a single self. To be sure, unity of a sort can be achieved by one who has a meager company of selves Narrowness, provincialism, bigotry, describe a personality in which unity of purpose is won at a sacrifice of breadth, outlook and sympathy The highest type of personality grows out of many far-reaching selves which have

[1] Commencement address of the president at the University of Wisconsin.

been selected and organized into unity by a dominant purpose. It is no easy task to unify often divergent and conflicting impulses, habits, memories and ideals into a harmonious hierarchy of aims. But such singleness of ideal and effort creates power. The man of purpose is not to be resisted. Every instinct and habit, every picture of the mind, every effort of the will, every emotion, fits into his scheme of things. He never wanders from the path which leads toward the end he has set up. He turns every opportunity to account. He foresees problems and is prepared to meet them. He confronts difficulties undaunted. He is master of a company ever devoted and responsive to command. The world submits to great men of single aim.

Education seeks just this unification of personality. Plato's philosopher was he in whose life reason aided by will kept appetite and passion in servitude to the higher aims of life. Sir Richard Jebb tells us that

> Education consists in organizing the resources of the human being. It seeks to give him powers which shall fit him for his social and physical world. . . . The educated person is able to deal with circumstances in which he has never been placed before. He is so because he has acquired general conceptions. His imagination, his judgment, his powers of intelligent sympathy, have been developed.

The ideal personality, then, includes many selves organized by a masterful purpose and unified by a spirit of harmony.

In many ways a human group, a family, a community, an institution, a nation, is like a personality. Hobbes saw the state as a vast Leviathan. Comte conceived humanity as an on-going continuous life which sweeps through the centuries. Bluntschli endows political society with the characteristics of a person. Contemporary philosophers attribute to society the mental and moral traits of a vast super-man. The analogy is not wholly fanciful. Just as purpose unifies the individual, so a common aim gives the human group a sense of solidarity. Social consciousness is the well-worn term for this thrill of comradeship. The sense of team play that makes the eleven or the nine an efficient unit gives us the type. Each individual sees the group as a whole, is aware of his own relation to it, knows that his fellows share his feeling, and counts upon them to act promptly for a common end. A group which can not control its members and rally them in loyalty to a single aim lacks solidarity and effectiveness.

So, too, a large inclusive group like the nation must subordinate the minor groups that make it up, must rally them to the service of the whole, must provide the ideals and the plans for gaining a national end. The story of modern Germany is eloquent of imperial purpose and of aims unswervingly pursued. Contrast the broken, humiliated German states after the battle of Jena with the unified, efficient triumphant empire of to-day. The names of von Stein, von Moltke and Bismarck spell purpose and policy, far-seeing, statesmanlike, remorselessly followed. These aims seem like vast independent forces, molding men and institutions to their service. Schools, army discipline, scientific research, technical skill, commercial resourcefulness, governmental efficiency, social legislation, are all well considered parts of one comprehensive, far-reaching national program. Against such a power a disorganized, untrained and undisciplined nation is impotent. The law of unification through purpose holds good whether the units be the impulses, thoughts and feelings of the individual, or the persons and groups that make up a great people. As we classify the powers

of the world we may value them for their contributions to the past, but their futures we measure in terms of social unity and national purpose. To a despondent observer our own nation at times appears to lack both unity and a clear vision of its task. Sections, classes, interests, parties, cliques, sects seem to the gloomy onlooker to give the lie to the idea of national unity. Faith in a glorious manifest destiny is not the same thing as a real sense of national purpose. But beneath all the discord and clash of antagonistic groups, and vaguely emerging from a fatalistic optimism, we discern an underlying loyalty to American ideals and a clearer conception of American aim and American duty. Our national greatness will depend upon the growth of loyalty and good will, and upon the working out of an ever clearer conception of America's part in the building of a nobler civilization.

As with the nation, so with the institution. Consciousness of itself, a sense of team play, loyalty to a common aim, make a university strong and efficient. But the university gets its meaning from society and from the nation and therefore must be an expression of the common life. In the words of Dr. Pritchett, "No nation is likely to be educationally efficient until it has grown into some fair possession of a national educational consciousness." The university is one of the agencies of national purpose. "The kings," writes President Jordan, "have recognized the need of universities and university men. In this need Alfred founded Oxford, and Charlemagne the University of Paris. The Emperor William is quoted as saying that 'Bismarck and von Moltke were but tools in the hands of my august grandfather.' To furnish more such tools and in all the range of human activity, the University of Berlin was established."

If the university, as an organ of society, is to gain strength of purpose it must have a consciousness of its function and duty. Only by such sense of team play can individuals, departments, schools, colleges, faculties, classes, student groups, be fused into genuine unity and rallied to a common loyalty. In general, the university ideal is changing from the thought of personal privilege to the conception of social service, from a preaching of personal culture to a democracy of studies, or in another phrase, from culture to efficiency. This does not mean that colleges and universities have not always had some sense of social obligation. But too generally the privileges of higher education were for the favored few who by virtue of their special opportunities were set off from the masses of men. The growth of democracy has made new demands, has widened opportunity, has broken down the barriers of class. Even in the old world, and notably in the new, democracy has created schools, colleges and universities and has chartered them to serve the common welfare. The university has become, therefore, especially in this mid-western region, "the people's organized instrument of research," or as President Van Hise puts it, "the scientific adviser of the state." On every hand we hear variations of this central theme of social service. College presidents and men in political life, each group from its own point of view, insist upon this conception of higher education. In this view the university appeals to the imagination, it becomes an organ of the higher life of the community and the state, it connects itself at every point with the industry, commerce, social conditions, educational interests, ideal purposes of the commonwealth.

The university as a social agent is entrusted with certain standards of the community, standards of scientific method and

of truth, standards of technical efficiency, standards of cultural attainment, standards of personal character and of civic duty. It is only through the creation, the guarding, the elevation of these standards that material and spiritual progress is possible. The university becomes a trustee of ideas and ideals, a custodian of standards In the administration of these standards the university can not sacrifice the common welfare to individual need or desire It must exclude those who fail to meet the standards of attainment and character which the university administers Favoritism, faltering, compromise, cowardice mean betrayal of a social trust Nor may the standards of the university be provincial and temporary In the words of President Hadley, "the university must be judged by the standards which have held for all time rather than those of a single generation, or of a single profession" The imagination kindles at this thought of a university exalting the tests of truth and character by which society slowly gropes toward higher levels

When the mind is possessed by this vision of the university, all the careers for which it provides training take on the dignity of social worth. Vocations which have been thought of as individual widen into literal calls to be servants of the common life The office of the teacher, the function of the physician, the work of the engineer, get their higher meaning from their value to the community. The profession of the law, so often thought of as a field for personal exploitation, is in its true significance a social service. "We lawyers," declares Woodrow Wilson, "are servants of society, officers of the courts of justice . . . guardians of the public peace, . . . bond servants of the people." The scientific farmer is in one view seeking personal gain, but in a much deeper sense he is diffusing knowledge and skill and is raising into higher esteem fundamental industry which makes modern society possible The college graduate who has received the training men are fond of calling liberal, may no longer regard himself merely as a member of a privileged class. In the new spirit of *noblesse oblige* he must recognize his obligation to his fellows and to the community, must remember that "life is not a cup to be drained, but a measure to be filled" Such is the ideal purpose which summons the modern university to unity and comradeship in the service of the common life When this vision fills the minds of all, when it controls their conduct, when it stirs their emotions and carries them steadily forward to loyal achievement, then the university gains an irresistible power and becomes a true expression of the higher purposes of the state, the nation and mankind.

As a general purpose, a settled character, a dominant spirit control the thoughts and impulses of the person, so the persistent aim and the enduring ideals of an institution influence and guide the individuals who compose it. The trustees of a university that is unified by the purpose of service must think of themselves as public officers entrusted with grave duties and heavy responsibilities No personal ambition or interest can enter where the spirit of trusteeship for the common welfare is the controlling ideal. Strong, resourceful men may well sacrifice their personal interests in responding to so high a summons. To administer a university wisely, with open mind to the public welfare, with sympathetic insight into the needs and inspirations of all classes of citizens, to safeguard academic freedom, to guarantee positions of dignity and satisfying activity to competent scholars—these are the duties and

opportunities of men who accept a great educational trust

Devotion to the common good lays upon members of the investigating and teaching staff duties they may not shirk To maintain worthy standards of scholarship, to be loyal to these ideals, to be faithful to the pursuit of truth, to conceive education in its widest and most generous aspects, to have sympathetic insights into the lives of their students, to spend themselves freely for the community—to these things the vision of the university as a public servant must draw the teachers and the investigators of a true university This is the call to the "scholarship whose devotees regard themselves as holding a trust for the benefit of the nation"

The university fails of its purpose if its students do not catch the inspiration of the common ideal To generous-minded young men and women this thought of the university must make appeal It is the duty of the institution to fix this image of the university in the imaginations of its students. From the day they enter to the day they leave, this dominant purpose, this persuasive spirit should grow ever more potent and fascinating. It would be well if students could begin their college life with formal ceremony so that at the very outset they might feel more keenly the social obligations they are assuming Admission to the university should seem to them initiation into a high calling It is a pity that they should begin for the most part thoughtlessly or with minds fixed solely upon personal aims and plans. The state is calling them to her service. She has a right to insist that only those who are in earnest, who have at least a dawning sense of social duty, should seek admission to the public training which can be justified only by its service to the state. It should be made clear that no one has the right to demand admission as a personal privilege. Conformity with technicalities of entrance must not blind us to the moral obligations involved Out of the common fund to which all citizens contribute the state erects and maintains not for personal advantage but for public good this West Point of science, the arts and the professions Every matriculant, therefore, by virtue of admission is honor bound to meet the state half way in her desire to prepare soldiers of science for the battles of peace. The university must unhesitatingly rid itself of individuals who are indifferent to intellectual work or hostile to it After fair test, those who fail to show their sense of the university's purpose must be dismissed This is necessary not only in justice to the state, but in fairness to those who show due appreciation of their opportunities and duties

The dominant university purpose gives a proper setting to the activities of student life and to the standards and conduct of the groups into which the student community naturally falls. The contacts of daily association and searching tests of comradeship, the discovery and development of leadership, the give and take of social intercourse, the healthy recreation of undergraduate life—all constitute an environment which may afford admirable discipline There is large truth in the assertion that the university is the world in miniature and that it offers a social training which will be turned to account in the wider life of the community. But all these activities must be tested by the dominant purpose of the university. The question must always be, is this or that out of harmony with the ideal of the university as an organ of the common life? Does this student demonstration or that rollicking festivity create in the public mind the feeling that the university is living for itself

and not for the community, does it foster the belief that the university is not dominated by the motive of service, does it create the suspicion that students ignore or forget their duty to the state which is making their self preparation possible? This is a vital question. So with the student groups that play so large a part in academic communities. Are these groups working loyally for the common welfare, have they due regard for the fundamental things of university life, are they actuated by a sense of responsibility for their members, do they cultivate tolerance, justice and good-will? These are questions which individuals and groups must constantly put to themselves and answer frankly and honestly. The good name of the university is safe only when its members feel an obligation to further the common purpose to make the university a true organ of the whole people.

So long as this spirit prevails, no sense of arrogance, of exclusiveness, of privilege or caste will enter the minds of its members. The old distinction of "town" and "gown," the traditional attitude of superiority toward those outside the walls of the academic cloister, these things have no place in an institution dominated by the spirit of social service. Every man and woman of the commonwealth becomes in this view a supporter and patron of the university, and may expect from it good-will and loyal service. If to say that the university belongs to the state is anything more than phrase-making, every member who has imagination, the power to see the institution in its real relationships, must feel the genuine humility of one who would faithfully serve his fellows.

If the university is to fulfill its function, it must carry conviction to the people of the commonwealth. It must impress them with its purpose, make them see it as a faithful agency of the people. The men and women of the state must not think of the university as an institution which, because it has public support, should lower its standards to admit the weak, indifferent or incompetent, or to graduate those who have failed to reach the minimum of attainment. People must not think of the university as a place in which personal influences can secure special privilege. Rather they must regard it as fearlessly loyal to the common welfare, true to high standards of scholarship, truth, efficiency, character and judgment. They must not ask or expect special favors from this servant of the whole democracy.

If the university purpose is to be achieved the institution must seek special ability wherever this is to be found. It would be a calamity if only sons and daughters of the rich and well-to-do could gain access to higher training. Talent and genius ignore the distinctions of wealth and class. A way must be found by which young men and young women of great promise, however they may be hampered by poverty, may gain access to the social training of the university, and be freed in large part or wholly from the self-supporting work which makes the best scholarship impossible. We must believe that men and communities will catch this vision of the university and by providing scholarships see to it that no exceptional ability shall be deprived of development for the service of the commonwealth. The university would lose its power and its ideals if it ever became a place of privilege for the well-to-do and not a training school for all who have talents and capacities for which the state has need. The controlling ideal, the mastering purpose of the university, therefore, is not a mere phrase or conceit, it is a guiding principle which finds application to every individual, to every group,

to every activity of academic life, and organizes these into the strength and unity which only a common aim can confer

Purpose steadily pursued creates a persuasive spirit, registers itself in institutional character Open-mindedness must be a conspicuous trait of a true academic community The very search for new knowledge, the effort to see the relations of things, presupposes an attitude of enquiry, a willingness to look at an idea or a fact from many different standpoints Open-mindedness toward truth merges into tolerance and mutual respect as between the individuals and groups who make up the university Narrowness or prejudice, a patronizing attitude of one group toward another, the discrediting of this calling as compared with that, the limiting of the conception of research to traditional fields of enquiry—these things have no place in an institution mastered by a sense of loyal duty to commonwealth and nation Genuine culture consists largely in sympathy with many kinds of men and in insight into the widest ranges of human life To live in a highly specialized community and to enter with appreciation into the activities of one's colleagues in many fields is in itself a liberalizing experience There is place for generous rivalry in a great university, but this rivalry must be kept on a high level and not allowed to sink into unworthy conflict and discord Open-mindedness, tolerance, high-minded rivalry can not fail, under the guidance of a controlling ideal, to fuse the university into a genuine unity of comradeship and good-will. When each man and each group can see, not only through its own eyes but through the eyes of other persons and groups, the common problems of the institution, there must develop a keener sense of team play, a quickened loyalty, a more vivid corporate consciousness

The university, a servant of the common life, exalting standards of efficiency and worth, summoning its members to a common task, must stand for the loftiest ideals It must inspire enduring faith It must exalt character above technical skill, mental alertness, refinement of feeling It must lay hold of the fundamental motives. The university rightly aims at leadership, but in the words of Dr Pritchett, it can win this "only by inspiring the youth of the democracy with a true, vibrant living faith The American university is today the home of that faith It is the faith of humanity in humanity and the American university, which embodies the intellectual aspirations of a free people, is becoming day by day the representative of their spiritual aspirations as well " The state university can not fulfill its true function unless it rises to the higher level of spiritual idealism It may not ally itself with any church or support any one theology, but it must draw its inspiration from an essentially religious view of life As the Sir Thomas More's Utopians tolerated many theologies of widely varying kinds, but united in common worship of the divine energy back of all nature and human life, so the university welcomes men and women of many faiths and rallies them to a devoted loyalty to common ideals of duty, service and reverent aspiration

In the "Republic" Socrates, in talking of testing the young for leadership, declares, "We must inquire who are the best guardians of their own conviction that the interest of the state is to be the rule of all their actions We must watch them from their youth upwards and propose deeds for them to perform in which they are most likely to forget or be deceived, and he who remembers and is not deceived is to be selected, and he who fails in the trial is to be rejected." The gentle sage goes on to

describe the tests of toil and pain, the tests of fear, the tests of seductive pleasures, and he tells us that "He who at every age as boy and youth, and in mature life, has come out of the trial victorious and pure, shall be appointed a ruler and guardian of the state. He shall be honored in life and death, and shall receive sepulcher and other memorials of honor, the greatest that we have to give."

The essentials of life and character have not changed since the days when Socrates talked of truth and justice in the groves of Academus. You graduates to-day go forth to be tested. You have in varying measure the vision of the university, the sense of obligation which your training lays upon you. You must hear, be it ever so faintly, the call to be servants of the commonwealth. Put to yourselves the question which comes down through the centuries, can you hold to this conviction that the interests of the community should be the rule of all your actions. You will face intellectual sophistry and beguiling fallacies. Have you the keenness of mind and the force of character to analyze these specious assertions and to hold steadfastly to things that are true and enduring? You will be tested by fear, fear of financial loss, fear of ridicule, fear it may be of social ostracism. Have you the courage and character to preserve your convictions of loyalty to the general good? You will be lured by pleasure, dazzled it may be by luxury and ostentation, tempted to self-indulgence and evanescent pleasures. Have you the fiber to resist these appeals and to remember that the social servant must be ever strong, clear eyed and faithful to his work?

May you hold to the vision you have caught: may it with the passing years grow ever clearer, brighter, more commanding in your lives. The university sends you forth to-day with God speed, entrusts to you the good name of our widening community, summons you to loyalty, urges you to organize all your resources of mind and spirit into the unity of a high aim, the firm resolve to realize in your own lives the masterful purpose of the university which is to be in ever fuller measure at once the standard bearer and the servant of the state.

Go to your work and be strong, halting not in a world of men,
Balking the end half won for an instant dole of praise.
Stand to your work and be wise—certain of sword and pen,
Who are neither children nor Gods, but men in a world of men.

GEORGE E. VINCENT

COURSES IN HIGHER PURE MATHEMATICS

THE number of the objects of mathematical thought is infinite and the rapidly widening range of developed mathematics is continually directing mathematical attention to objects which were previously either practically or entirely ignored. Efforts to classify mathematics have been only partially successful and it is extremely difficult, in many cases, to draw reliable conclusions as to the nature of a course from its title. Hence the efforts to ascertain from the announcements of the leading universities of the world the relative emphasis which different countries place on the various subjects of higher mathematics can not be expected to lead to entirely trustworthy results.

The rapid development of our universities has led to such a rapid increase in the number of different mathematical courses beyond the first courses in differential and integral calculus, that many well-educated people have failed to keep informed as regards the general meaning of the titles of some of these courses. This is perhaps not surprising in view of the fact that several of our strongest universities offer their advanced courses under more than thirty different titles.

This great number of titles of courses implies that many of them are devoted to comparatively narrow fields and raises the question whether we are not in danger of specialising too much and of depriving our students of a thorough training in the more general and fundamental methods of wide contact. It would probably be generally conceded that we have gone further in the line of special courses than the universities of Germany, which were pioneers in this direction. On the other hand, it may be observed that the large German and French mathematical encyclopedias which are in the course of publication treat pure mathematics under about one hundred general headings, each of which would be sufficiently extensive for a course suitable for graduate students.

This great extent of available material makes it impossible for one student to cover even superficially the entire field during his college days and hence it tends to increase his interest in a wise choice of his courses, especially as regards such courses as are most generally given and are most likely to be very useful in his later mathematical development. One of the most reliable sources of information along this line is furnished by the number and the extent of the courses devoted to different subjects in the various leading universities.

Various journals, including the *Bulletin of the American Mathematical Society*, are publishing, from time to time, lists of announcements of the courses offered by a large number of different universities of Europe and America. A comparative study of these announcements for a period of years involves a large amount of labor in view of the changes from year to year and the uncertainty as to the real significance of some of the titles. As American mathematical activity has been so largely influenced by Germany, especially during recent years, and as the University of Berlin occupies such a prominent place among the greatest centers of learning, it may be fitting to begin with some results drawn from the announcements of this university during the last six years.

The following table gives only those courses in pure mathematics to which the equivalent of at least twelve lecture hours for one semester have been devoted during the last six years. A large number of special courses have thus been excluded. For instance, one of the courses offered only once during the period covered by the table bears the title, "Transcendental Nature of π and e," another is announced under the title "Influence of Euler's Work on Modern Mathematics," while still another bears the title "Problems in Maxima and Minima treated by Methods of Elementary Geometry." No course bearing the title "Differential Geometry" was offered at Berlin during the period under consideration, and only one course entitled "Linear Substitutions." A large part of the subject matter of such courses was, of course, given in the courses under more general titles. Similar remarks apply to a large number of other subjects. The number of hours devoted to seminars and colloquia was not included in the following table as the subject matter of these exercises was not always clearly announced.

BERLIN UNIVERSITY

Subjects	Lecture Hours for Six Years	Totals
Curves and surfaces	4, 11, 8, 8, 8, 13[1]	52
Theory of functions	4, 6, 0, 8, 10, 12	40
Determinants, theory and applications	4, 8, 4, 4, 8, 6	34
Theory of numbers	4, 4, 8, 8, 4, 2	30
Elliptic functions	4, 4, 4, 8, 8, 2	30
Algebraic equations	0, 4, 8, 4, 6, 4	26
Differential equations	0, 4, 6, 4, 6, 4	24
Algebra	4, 4, 0, 4, 0, 4	16
Calculus of variation	0, 4, 4, 0, 0, 4	12

It may be observed that the total number of hours devoted to the four subjects belonging to arithmetic and algebra is 106, while the total numbers of hours devoted to analysis and geometry are 98 and 52, respectively. As we shall see later, these results are not in accord with those obtained in a similar man-

[1] The last of these numbers applies to the current year, and the numbers which precede relate to the preceding years in order.

ner from many other universities and they would be slightly changed at Berlin if all the courses in pure mathematics had been tabulated. They would also have been affected by the consideration of the courses on applications of mathematics. As is well known, a large number of courses on applications of elliptic functions are given at Berlin. These are in addition to the courses on the theory of these functions as listed above, and during the six years under consideration the number of lecture hours devoted to these applications in Berlin University were, respectively, 6, 0, 10, 0, 8, 4—making a total of 28. Hence a total of 58 lecture hours for a semester were devoted to elliptic functions and their applications during these six years—an average of nearly five hours for each semester.

Among the other German universities which maintain very strong mathematical departments Gottingen should perhaps be especially mentioned in view of the facts that so many Americans have studied there and the influence of Klein and Hilbert has been so great in shaping our courses in higher mathematics. It may also be desirable to bring the mathematical courses of the universities of Berlin and Gottingen together in view of the fact that they exhibit a great difference as to emphasis on the various subjects of pure mathematics. For instance, only two courses on determinants and their applications were given at Gottingen during the last six years while at Berlin this course has been given very frequently, as may be seen from the table given above.

At Gottingen courses on differential equations have been given very much more frequently than at Berlin, while courses on elliptic functions are much more common at the latter institution than at Göttingen. Judging from the number and the extent of the courses, there is a very wide difference between Berlin and Göttingen as regards the emphasis on the subjects which are usually classed under the general headings, algebra and analysis; or arithmetic and algebra, and analysis. At Berlin the former receive very much more attention than at Göttingen and the predominating influence of the latter institution is evident in the advanced mathematical courses of many American universities. A marked difference between Gottingen and Berlin may also be observed with respect to the tendency to give courses under a large variety of names. At Gottingen we find a larger number of courses under such titles as, encyclopedia of geometry, encyclopedia of elementary mathematics and elementary mathematics from a higher standpoint, than at Berlin.

In the following table we give again only those courses to which at least twelve lecture hours for one semester have been devoted during the last six years, excluding courses which appeared to have been devoted mainly to applications, and arranging the others in the order of the number of lecture hours.

GÖTTINGEN UNIVERSITY

Subjects	Lecture Hours for Six Years	Totals
Differential equations	12, 12, 12, 8, 11, 4	59
Theory of functions	7, 0, 8, 6, 10, 8	39
Descriptive geometry	4, 4, 0, 8, 0, 8	24
Algebra	4, 0, 4, 4, 4, 4	20
Theory of numbers	4, 0, 2, 4, 3, 4	17
Calculus of variations	4, 4, 1, 4, 0, 2	15
Curves and surfaces	7, 4, 2, 0, 0, 0	13
Principles of mathematics	0, 0, 4, 2, 2, 4	12

A comparative study of the courses offered in other German universities reveals wide differences as regards emphasis on the various subjects and such a study tends to explain the migration of students from one institution to another. Unfortunately, there is very little migration in American universities, and hence our students are frequently acquainted only with the courses offered by one institution. This makes it the more desirable that our large universities should aim to offer a wide range of subjects, covering the most important parts of the various developed fields of mathematics. It is evident, however, that it would be much better if our students could be induced to divide their time of graduate study among different universities and to seek instruction under the foremost men along the lines of their chief interests.

It is of great interest to consider the difference between the emphasis placed on various subjects by different countries A comprehensive study of this difference becomes, however, quite difficult in view of the fact that the different countries vary widely as regards the line of division between their university courses and those treated earlier It is, however, not difficult to establish certain decided differences A slight study reveals the fact that American universities are unusually weak, on an average, with respect to courses on elliptic functions, general mathematics and theory of numbers, while the relative number of our courses in the theory of groups, theory of functions, and differential geometry is above the average These results are deduced from a fairly extensive tabulation of the courses in mathematics which Professor J B Shaw recently presented before the Mathematical Club of the University of Illinois In particular, Professor Shaw listed the courses of all German universities for a period of six years and found that during this period the number of lecture hours devoted to courses in the three great fields of pure mathematics—algebra, analysis and geometry—were in the proportion 193, 259 and 200, respectively

G A MILLER
UNIVERSITY OF ILLINOIS

WILLIAMINA PATON FLEMING

MRS. WILLIAMINA P FLEMING, curator of astronomical photographs at the Harvard College Observatory, was born in Dundee, Scotland, on May 15, 1857, and came to this country soon after her marriage in early womanhood. She soon drifted into the work which was destined to occupy her life, by undertaking some simple astronomical calculations at the Harvard Observatory, where, upon her death on May 21, 1911, she had just completed thirty years of service These thirty years have covered a period of remarkable changes in the methods of attacking astronomical problems. The prism has revealed to us something of the nature of the heavenly bodies, and the photographic plate has made a permanent record of the condition of the sky, which may be studied at any time Celestial photography was systematically undertaken at Harvard in 1882, by Professor E C Pickering, the present director The work was placed on a firm basis by the liberality of Mrs Draper in establishing the Henry Draper Memorial, and in a short time, photographs were being taken in large numbers The Harvard photographic library now contains over 200,000 plates

Mrs Fleming's duties were to qualify these plates, superintend their care, examine them for peculiar objects, and make investigations by means of them Each plate must be so indexed that it can be found at any time, and must be carefully handled and stored, being of fragile glass, and without a duplicate With a naturally clear and brilliant mind, Mrs Fleming at once evinced special aptitude for this photographic investigation, which was so novel that precedents could not be found for its execution, and, in return, the photographs proved to be veritable mines of wealth for the extraction of information concerning the sidereal universe Most of Mrs Fleming's discoveries were made from the spectrum plates which are taken by means of a prism placed before the object glass of the telescope, and which often show the spectra of several hundred stars She examined with a magnifying glass, all these plates taken at Cambridge and at the Harvard southern station in Arequipa, Peru, and marked all objects showing any peculiarities in their spectra In this way, she found ten new stars and more than three hundred variable stars, because of the presence of bright lines in their spectra She classified the spectra of 10,351 stars, which were published in 1890 in a volume of the *Harvard Annals*, called the "Draper Catalogue of Stellar Spectra." When stricken with the fatal illness, she was at work on a Memoir on Peculiar Spectra, which will give useful tables and much additional information concerning many interesting celestial objects. Much of her time was always occupied by tedious work upon the proof of the numerous volumes of the Annals

published by the Observatory during the last twenty-five years. Her diligence and patience were combined with great self-reliance and courage. She was a member of the Astronomical and Astrophysical Society of America, and of the Astronomical Society of France. The British Royal Astronomical Society made her an honorary member in 1906, and soon after, she was appointed Honorary Fellow in Astronomy of Wellesley College. Only a few months ago, the Astronomical Society of Mexico presented her with a gold medal for her discovery of new stars.

She left one son, Edward P. Fleming, who graduated from the Massachusetts Institute of Technology in 1901, and is now a mining engineer in Chile.

Of a large-hearted, sympathetic nature, and keenly interested in all that pertains to life, she won friends easily, while her love of her home and unusual skill in needlework, prove that a life spent in the routine of science need not destroy the attractive human element of a woman's nature.

ANNIE J. CANNON

HARVARD COLLEGE OBSERVATORY,
CAMBRIDGE, MASS.,
June 3, 1911

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION

THE program of the Pittsburgh meeting on June 27, 28 and 29, is as follows.

TUESDAY. Meetings at the School of Applied Science, Carnegie Technical Schools.

At 9.45 A.M. Address of welcome by Director A. A. Hamerschlag and response by President A. N. Talbot.

"Teaching English in Technical Schools," Professor S. C. Earle, Tufts College.

"The Preparation of Written Papers in Engineering Schools," Professor F. N. Raymond, University of Kansas.

"The Use of Logarithmic Diagrams in Laboratory Work," Mr. H. A. Gehring, Department of New York State Engineer.

"Highway Engineering," Professor A. H. Blanchard, Brown University.

At 2:00 P.M. Report of Committee on Teaching Mathematics to Engineering Students, Professor E. V. Huntington, Harvard University.

"Balance of Courses in Chemical Engineering," Dean C. H. Benjamin, Purdue University.

"Chemical Education for the Industries," Professor J. H. James, Carnegie Technical Schools.

A visit to the Country Club, followed by a dinner tendered by Director Hamerschlag on behalf of the Carnegie Technical Schools. During the evening President A. N. Talbot delivered his presidential address on the subject, "The Engineering Teacher and his Preparation."

WEDNESDAY. Meetings at the School of Applied Science, Carnegie Technical Schools.

At 9.30 A.M. Report of the Committee on Entrance Requirements, Professor J. J. Flather, University of Minnesota, chairman.

"All year Session, Individual Instruction: Renewed Suggestions," Dean W. G. Raymond, University of Iowa.

"The Architecture of Engineering Schools," Professor J. M. White, University of Illinois.

"The Wentworth Institute," Director A. L. Williston, Wentworth Institute.

At 8.30 P.M. Executive session of the society and election of officers.

"The College Campus," illustrated lecture by Professor J. M. White, University of Illinois.

THURSDAY. Meetings at Thaw Hall, University of Pittsburgh.

At 9.15 A.M. Address of welcome by Chancellor S. B. McCormick and response by President A. N. Talbot.

"An Engineering Course for Underclassmen," Professors W. A. Hillebrand and S. B. Charters, Jr., Stanford University.

"Electrical Engineering Instruction," Professor E. B. Paine, University of Illinois.

"Teaching of Scientific Shop Management, with Use of Engineering School Shops as the Laboratory," Professors H. Wade Hibbard and H. S. Philbrick, University of Missouri.

"Technical Training from the Business Man's Standpoint," Mr. E. B. Raymond, vice-president of the Pittsburgh Plate Glass Co.

"Adapting Technical Graduates to the Industries," Messrs. C. F. Scott and C. R. Dooley, Westinghouse Electric and Manufacturing Co.

"Cooperative System of Engineering Education at the University of Pittsburgh," Dean F. L. Bishop, University of Pittsburgh.

At 8:30 P.M. Assemble in foyer of Carnegie Music Hall. The Pittsburgh alumni of engineering colleges were invited to meet the representatives of the faculties from their almæ matres. A brief program was rendered upon the organ

in Music Hall, after which the members visited the Department of Fine Arts and the Museum of the Institute

FRIDAY AND SATURDAY

Members are invited to remain in Pittsburgh after the close of the convention to make further visits among the industries described in the hand book Specific arrangements may be made for these visits at the secretary's office during the meeting Special arrangements were made for the benefit of visitors in a number of cases, notably the Bureau of Mines, the Jones & Laughlin Steel Company, the Mesta Machine Company, the National Tube Company, the Westinghouse Electric and Manufacturing Company and the Westinghouse Machine Company It is expected that engineers will be detailed to guide the visitors, and that, in some cases, special exhibits and tests will be provided

INDIANAPOLIS MEETING OF THE AMERICAN CHEMICAL SOCIETY

THE Indiana Section made special efforts toward an unusually successful meeting beginning June 27 and lasting throughout the remainder of the week. The program was arranged as follows

The council will meet on the afternoon of Tuesday, June 27, and after a business meeting will be taken for an automobile ride to the Indianapolis Speedway

On Wednesday, the general session will begin and three general addresses will be given Professor Charles Baskerville, of the College of the City of New York, will give an address on "The Chemistry of Anesthetics" Professor Edward Kremers, of the University of Wisconsin, will follow with a paper on "The Quinhydrone Hypothesis of Plant Pigmentation." The third address, by Professor W. Lash Miller, of the University of Toronto, will be upon "The Chemical Philosophy of the High-school Text-books" These papers will be followed by a complimentary luncheon at the German House and after luncheon meetings of the agricultural and food, industrial, organic and physical and inorganic divisions and the biological section will be held. In the evening a complimentary smoker will be held in the gardens of the German House.

On Thursday morning there will be meetings of the agricultural and food, industrial, organic, pharmaceutical and physical and inorganic divisions, one of the special features being the meeting of the pharmaceutical division in the new science building of the Eli Lilly & Co, followed by a luncheon there to the pharmaceutical chemists. At the same time a complimentary luncheon will be given to the remaining chemists at the Indianapolis Brewing Co, followed by an inspection of their plant In the afternoon all of the chemists will visit the plant of the Eli Lilly & Co On Thursday evening there will be a public lecture by Mr. A D Little at the German House on the "Earning Power of Chemistry" This lecture is one of the features of the meeting and is intended to interest chemists, business men and the general public alike. Following the lecture there will be a concert in the gardens of the German House

On Friday there will be an early visit to the Indianapolis Water Works followed by meetings of the fertilizer, industrial, physical and inorganic divisions and the sections of biological and of india rubber chemistry At 12·30 these will be followed by a complimentary luncheon at the automobile factory of Nordyke & Marmon, followed by an inspection of their factory. Later in the afternoon visits will be made to the Encaustic Tile Co., to the Fairmount Glass Works and to E C. Atkins & Co In the evening the usual banquet of the summer meeting will be held

On Saturday there will be visits to the Kingan & Co, Ltd., to the Polk Sanitary Milk Co and to the Diamond Chain Co., in the afternoon, to the Van Camp Packing Co.

A special endeavor is also being made to see that the ladies accompanying members have an enjoyable summer outing, including automobile rides, receptions, theater parties and luncheons.

Over one hundred and fifty papers have already been received for the divisional meetings.

CHARLES L. PARSONS,
Secretary

SCIENTIFIC NOTES AND NEWS

AMONG the honorary degrees conferred by Yale University are doctorates of laws on Dr Josiah Royce, professor of philosophy at Harvard University, and Dr George E Vincent, president of the University of Minnesota, the doctorate of science on Professor W. H Howell, professor of physiology in the Johns Hopkins University, and the doctorate of letters on Mr John Muir, naturalist and author

DR EDGAR F SMITH, provost of the University of Pennsylvania, has been given the doctorate of laws by Rutgers College

THE doctorate of science has been conferred by Wesleyan University on Dr F G Benedict, director of the Nutrition Laboratory of the Carnegie Institution and by Tufts College on Dr A P Wills, professor of mathematical physics in Columbia University

THE University of Pennsylvania has conferred an honorary doctorate of veterinary medicine on Dr. Veranus A Moore, of the State Veterinary Department of Cornell University.

BROWN UNIVERSITY has given a doctorate of science to Dr. H J Wheeler, director of the Experiment Station of the Rhode Island College, and the master of arts to Mr F E Seagrave, astronomer, of Providence.

PROFESSOR FRANKLIN W HOOPER, director of the Brooklyn Institute of Arts and Sciences, has received the doctorate of laws from Middlebury College

THE London Mathematical Society has awarded the De Morgan medal for 1911 to Professor H Lamb, F R S, for his work in mathematical physics.

MR LEONHARD STEJNEGER has been appointed head curator of the department of biology in the U. S National Museum to succeed Dr. F W. True.

THE board of scientific directors of the Rockefeller Institute for Medical Research announce the following appointments to the staff of the institute:

Alfred E. Cohn, M D., associate in medicine.

Arthur N. M Ellis, M B., assistant resident physician.

Alphonse R Dochez, M D, assistant resident physician

Frank W Bancroft, Ph D, associate in experimental biology

Reinhard H Beutner, Ing D, assistant in experimental biology

James B Murphy, M D, assistant in pathology

J J Bronfenbrenner, fellow in pathology

Frederick B La Forge, Ph D, assistant in chemistry

Henry K Marks, M D, assistant in pathology

Helen L Fales, research scholar in chemistry

Angelia M Courtney, assistant in chemistry

PROFESSOR F W SARDESON, of the department of geology of the University of Minnesota, has been appointed geologist on the U S Geological Survey He has been directed to complete the areal, stratigraphic, and glacial geology of Minneapolis, St Paul, Anoka and White Bear quadrangles and to prepare a folio descriptive of this region for publication

PROFESSOR HERBERT E. GREGORY, of Yale University, has gone to Arizona in the interests of the United States Geological Survey in order to continue his study of the water supply and economic resources of the Navajo Reservation. He will be assisted in this work by Professor W. R Barrows, Mr. K C Heald, of Colorado College, and Mr H F Robinson, irrigation engineer of the Indian Service.

THE International Seismological Association will hold its regular meeting in Manchester, England, from July 18 to 22 The United States is a member of this association, and will be represented at the meeting by Professor Harry Fielding Reid, of the Johns Hopkins University

DR. L. MURBACH, head of the department of biology in the high school of Detroit, Mich, has been given a year's leave of absence. His address will be Castleton, Vermont.

DR JOHN MILNE, F.R.S., has been appointed Halley lecturer at Oxford for the year 1912.

ON June 13, Professor Ernst Cohen, of the University of Utrecht, gave an illustrated lecture before the Faraday Society on "Allotropic Forms of Metals." Professor T. W.

Richards, of Harvard University, was invited to take the chair

DR I W BLACKBURN, professor of pathology in the Georgetown Medical School, and of morbid anatomy in the George Washington University, and for twenty-seven years pathologist in the Government Hospital for the Insane, died on June 19, aged 60 years

THE United States Civil Service Commission announces that the Philippine government desires to fill two vacancies in the position of chemist, division of organic chemistry, Bureau of Science, Manila, P I, at salaries of $2,000 each per annum It is desired to secure the services of two young men between twenty and forty years of age with a high grade of scientific training who are capable of original work A thorough training in general and organic chemistry at a reputable college or university and experience in organic research is a prerequisite for consideration for this position, a Ph D degree from a leading university would be preferable A certain share of the routine work for the government would devolve upon the persons appointed to these positions, but the history of the laboratory in the past has shown that each man has had ample time for himself to do research work. In general, the men would select their own topics for investigation, such topics, of course, to have some bearing upon the development of the Philippine Islands. Facilities for immediate publication of research work are found in the *Philippine Journal of Science*, which represents the Bureau of Science before the world The attention of persons well trained and experienced in organic chemistry is especially invited to these vacancies since, if persons of the desired qualifications are secured, the prospects of promotion for both will be good, as one will probably succeed to the position of chief of the division of organic chemistry at $3,000 per annum within a year or two As applications for this position will not be received after August 1, 1911, those interested should communicate with the U. S Civil Service Commission at Washington, D. C, before this date

IT is announced by Dr Edgar L Hewitt, director of American archeology for the Archeological Institute of America, that the valuable library of the late German linguist, Professor Franz Nikolaus Finck, is to be brought to this country It has been purchased by the Hon Frank Springer, of New Mexico, for the use of the School of American Archeology, the research school of the Archeological Institute of America The library is to be installed in the historic palace at Santa Fe, where the Museum of New Mexico and the School of American Archeology are now housed

AT the Field Museum of Natural History, several new groups of American mammals have been placed on exhibition. The prong-horned antelope is shown by five animals in a setting of agaves, cacti and other vegetation of the arid southwest with a large painted background showing other natural features Four groups of small mammals include the white-footed mouse, jumping mouse, meadow mouse and short-tailed shrew. These are grouped, respectively, on the four sides of a reproduction of a bit of woodland with logs, bushes, grass and flowers so arranged as to form an effective and characteristic background for each

THE Sproul Observatory was dedicated at Swarthmore College on June 6 It has been presented by Senator William C Sproul, as a memorial of the twentieth anniversary of the class of '91, of which he is a member The exercises consisted of the address of presentation, in behalf of the class, by Congressman A Mitchell Palmer, '91, the unveiling of the tablet by Miss Dorothy Sproul, daughter of the donor, the speech of acceptance, by Dr John A Miller, professor of mathematics and astronomy, an address by Miss Susan J. Cunningham, formerly in charge of the same department, and a poem, "Watching the Stars," written for the occasion, by J. Russell Hayes The new observatory is expected to be ready for use next fall The telescope, the lens of which will have a diameter of 24 inches, will be one of the most effective on the Atlantic coast

An expedition to southeast Arabia has been planned by the Danish Royal Geographical Society, the object being the mapping of parts of Oman and the studying of the ancient memorials and commercial prospects of the country.

A cablegram has been received at the Harvard College Observatory from Kiel, stating that Wolf's Periodic Comet was observed by Professor Max Wolf at Heidelberg, June 19, 1911, 4792 m.

R A $18^h 46^m 16^s$
Dec $+ 13° 28'$

The comet is visible in a large telescope

The second annual midsummer State Farmers Institute will be held at the University of Illinois on Tuesday, Wednesday and Thursday, July 11, 12 and 13 The attendance at last summer's institute was about 2,500. Addresses to the general session will be given by the following:

Hon J K Dickinson, secretary, State Board of Agriculture, on "Agricultural Advancement"

Professor J H. Skinner, dean of the College of Agriculture, Purdue University, on "Rural Problems and Rural Progress"

Hon B F Harris, president of the Illinois Bankers' Association, on "The Banker Farmer, his Influence on Agriculture"

Dr Charles E Marshall, Michigan Agricultural College, on "The Farmer and the Scientist"

Hon W. E. Morse, assistant general manager, Chicago Northwestern R. R., on "Advantages of Closer Cooperation between the Railroads and the Farmer."

The following geologic investigation is being carried on in Oklahoma: Professor D. W. Ohern, of the University of Oklahoma, and Mr. Carl D. Smith, of the U. S. Geological Survey, are conducting cooperative parties in the Vinita and Claremore quadrangles in the northeastern part of the state. Professor C. H. Taylor, of the University of Oklahoma, is studying the igneous rocks of the Wichita and Arbuckle Mountains. Professor J. W. Beede, of the University of Indiana, has a party in the northern part of the state and will endeavor to trace out the Pennsylvanian-Permian contact from the Kansas line to the Arbuckle Mountains. Professor C. A. Reeds, of Bryn Mawr College, who has already spent four years in the Arbuckle Mountains, will continue his studies in the lower Paleozoic rocks of that region. The Ohern, Smith and Taylor parties are cooperative; being maintained by the U. S Geological Survey and the Oklahoma Geological Survey, the Beede and Reeds parties are under the direction of the Oklahoma Geological Survey The U S. Geological Survey, the Oklahoma Geological Survey and the Oklahoma State Board of Agriculture are cooperating in the endeavor to ascertain whether or not potash or other soluble salts are present in the western part of the state A number of deep wells are being drilled, under the direction of the state board of agriculture, in the Panhandle of Oklahoma, in the hope of finding artesian water. The federal Geological Survey and the Oklahoma Survey are paying the expenses of a man to collect samples at frequent intervals from these wells These samples will be analyzed for potash or other fertilizer material Mr. Chas R. Eckes has charge of the work

UNIVERSITY AND EDUCATIONAL NEWS

Princeton University has received gifts amounting to more than $100,000, of which $40,000 is for a lectureship in public affairs to be held by the Hon. George B. McClellan

Dr. Robert A. Harper, professor of botany, in the University of Wisconsin, has been elected Torrey professor of botany at Columbia University.

New appointments and promotions at the Johns Hopkins University are as follows: In the Philosophical Faculty· Harry F. Reid, Ph.D., now professor of geological physics, to be professor of dynamic geology and geography; John A. Anderson, Ph.D., now associate, to be associate professor of astronomy; Knight Dunlap, Ph.D., now associate, to be associate professor of psychology; J. Elliott Gilpin, Ph.D., now associate, to be associate professor of chemistry; William Kurrelmeyer, Ph.D., now associate, to be associate

professor of German; B Franklin Lovelace, Ph.D., now of the University of Alabama, to be associate professor of chemistry, Samuel O Mast, Ph D, now of Goucher College, to be associate professor of zoology, August H Pfund, Ph.D, now associate, to be associate professor of physics, Charles F Meyer, A B, now fellow, to be assistant in applied electricity, Chester N Myers, Ph D, to be assistant in chemistry In the Medical Faculty Thomas R Boggs, M D, now associate, to be associate professor of medicine, Charles D Snyder, Ph D, now associate, to be associate professor of physiology, Frank J Sladen, M D, now instructor, to be associate in medicine, William E Burge, Ph D, now assistant, to be instructor in physiology, Karl M Wilson, M D, now assistant, to be instructor in obstetrics, Solon A Dodds, M D, to be assistant in obstetrics, Eli K Marshall, Jr, Ph D, to be assistant in physiological chemistry, Isaac R Pels, M D, to be assistant in dermatology; Maxwell Ross, M D, to be assistant in medicine

FACULTY additions and promotions in Adelbert College and the College for Women of Western Reserve University have been made as follows· Harry William Springsteen, assistant professor of physics, to be associate professor of physics, Clinton Raymond Stauffer, Ph.D., associate professor of geology, James K Whittemore, M A, appointed assistant professor of mathematics; Walter Edward Sullivan, M A., instructor in biology. Faculty promotions and appointments in the medical department were made as follows. George Washington Crile, Ph D, M D, formerly professor of clinical surgery, was appointed professor of surgery; Carl August Hamann, M.D., formerly professor of anatomy, was appointed professor of applied anatomy and clinical surgery, Davidson Black, M.B, was appointed associate in histology and embryology.

IN the University of Michigan Museum, Dr. A. G. Ruthven has been promoted to be assistant professor of zoology and head curator of the museum; Miss Crystal Thompson has been made assistant in the museum. In the Department of Zoology, Dr. A. F Shull, of Columbia University, has been made instructor in zoology, in place of Assistant Professor A S Pearse, who has become assistant professor of zoology in the University of the Philippines, Dr George La Rue, of the University of Illinois, has been made instructor in zoology Assistant Professor O C Glaser has been granted leave of absence during the first half of the next academic year

AT Rutgers College instructors have been appointed as follows F F. Couch, M.E (Lehigh), in mechanical engineering, Floyd E Chidester, Ph D (Clark), in biology, and Harry R Lewis, B Sc (Rhode Island), in dairy husbandry

FRANK A. MANNY, of the education and extension departments of the Western State Normal School, Kalamazoo, Mich, has been appointed director of the training of teachers in the city of Baltimore

THE trustees of the University of Pennsylvania at a meeting held on June 12, 1911, advanced Dr John W Harshberger from assistant professor of botany to professor of botany.

DISCUSSION AND CORRESPONDENCE

THE DISEASES OF ECONOMIC PLANTS

THE recent review of "Diseases of Economic Plants" by Dr W A Orton[1] contained statements which I feel impelled to controvert, not in justification of the book, but in order to place the facts in their proper bearing before the readers of SCIENCE, lest some not technically informed should be led into erroneous conclusions by misstatements *ex cathedra*.

Some of his criticisms are merely matters of personal opinion, as, for example, his views on the use of the termination "ose" in naming diseases. This method was first suggested several years ago in a committee report before the American Association for the Advancement of Science, Section G, with Dr. Halsted as chairman. It has been used to

[1] SCIENCE, April 21, 1911, 621

some extent in this and other countries for years, and while some pathologists do not favor it, many others do. Moreover, Dr. Orton himself, in a letter,[2] writing on this point, says, "I would even make use of the new terminology in cases where no other suitable common name is available."

His mention of "more serious errors" deserves attention. Here he objects to considering *Microsphæra alni* as a destructive parasite, saying, "This fungus is one of the least harmful of the pecan parasites." Fawcette[3] quotes Mr. W. A. Munsell, of Florida, as saying that this fungus "had practically destroyed the pecan crop the year before."

Orton says, "The injury to tomatoes from *Phytophthora* is overstated." We stated that "It is very injurious, causing complete devastation of the crop in some sections and resulting in the loss of many thousands of dollars."

Authority for this may be found in the statement of R. E. Smith,[4] a very careful and reliable worker, who says, "During the fall of 1907 the whole acreage of tomatoes was completely ruined in this manner (by *P. infestans*) before active shipment had begun, making the crop a total loss." Also "in the district mentioned the shipments fell off within a very short time, from 2,000 crates a day to practically nothing . . . many thousands of dollars were lost."[5]

Orton himself[6] says of this disease, "Quite common in Massachusetts . . . reported also in southern California, where it caused large losses to the winter crop."

Orton says, "Absurdly large losses are attributed to cotton anthracnose in Georgia."

Our words are:

> The disease is very destructive in some localities and prevails throughout a large portion of the cotton belt. In central Georgia it is said to destroy about 22 per cent. of the crop yearly, sometimes more, while to the state as a whole the loss is put at 17 per cent. or approximately $14,750,000.

I may here quote the following:[7]

> From middle to north Georgia the gradual decrease in per cent. of the crop destroyed is from 22 per cent. to about 12 per cent. and to south Georgia, from 22 per cent. to about 4 per cent. It is conservatively estimated that the anthracnose costs the farmers of the state at least 17 per cent. of the cotton crop. 1,800,000 bales are gathered in Georgia, which represents then, only 83 per cent. of the crop that should be made, the other 368,900 bales representing the actual loss. This valued at $40 a bale would be $14,756,000 loss in money.

De Loach, the author of this statement, in a recent letter says:

> My statistics carefully taken in sixteen counties of the state of Georgia, in 1906 and 1907, and amounting at the least to 2,000 bolls in a locality, prove clearly to me that for those years my figures were quite conservative. I always selected representative localities and fields, and was making the survey for no other purpose but to estimate the actual loss to the growers incurred by this disease. In several instances in Spalding and Hart counties there was 80 per cent. of the bolls infected, but of course not this per cent. actual loss, as many of the bolls were half good and half diseased.

Orton says: "The description of Bordeaux injury is incorrect, as is also the statement that blossoms are killed and the lives of bees endangered."

As to Bordeaux killing bees it must be recollected that apple spraying is the topic under discussion; that the only time bees would be injured is while the tree is in blossom; that when the tree is in blossom arsenicals are almost invariably used in the spray, hence to spray during blossom is, in practise, dangerous to bees.

The description of Bordeaux injury given in the book is drawn largely from the writings of Hedrick,[8] who wrote his description follow-

[2] February 14, 1910.

[3] Fawcette, H. S., Fla. Agr. Expt. Sta. Rept., 1907, LI.

[4] Report Cal. Agr. Expt. Sta., Bull. 203, p. 44.

[6] Yearbook, 1905, p. 608.

[7] Ga. Agr. Exp. Sta., Bull. 85, Tech. Ser., 3.

[8] Geneva Bull., 287, pp. 107–108, Nos. 7, 10 and 11.

ing long experience with Bordeaux injury, a personal experience that is certainly far more extensive than that of Dr Orton I quote here a recent letter from Hedrick bearing on this point

> I have just gone over the description you give of bordeaux injury in your "Diseases of Economic Plants" and in my bulletin on the subject I can find nothing whatever to criticize in the statement you make in regard to this trouble I may say that since my bulletin was published, I have had occasion to give a good deal of attention to Bordeaux injury and do not believe that I would now describe it differently than when the bulletin was written My colleague, Professor Stewart, whom of course you know, and who has also given Bordeaux injury a good deal of attention, has just looked over your description and finds nothing to criticize in your discussion of the injury in question

It is gratifying to know that in these "more serious errors" the text of the book does not deviate widely from a basis, founded on exceedingly good authority, authority in some instances, most instances in fact, as trustworthy as that of our critic

Dr Orton was requested to read and criticise the manuscript of our book prior to its publication This he, with apparent willingness, agreed to do The manuscript of a large portion of the book, including most of the part under discussion, was submitted to him and certain criticisms were received, some of which were accepted, some not, according to the judgment of the authors. For all of this the authors are grateful to Dr Orton

That Dr Orton is much more aggressive and much more searching in this recent public criticism, *after publication, than in his private criticisms prior to publication* may, however, be shown by two quotations as well as by many other adduceable facts.

From letter February 16, 1910, "you already have a discussion of the most important non-parasitic diseases"

From review in SCIENCE, April 21, 1911, "The wilt and die back of the orange are omitted, as is the curly top of beet, one of the two most important maladies of that crop"

F. L. STEVENS

SCIENTIFIC BOOKS

The Stone Age in North America By WARREN K MOOREHEAD, A M Two volumes of 874 pp, 7 in by 9¾ in, 17 plates, 4 of which are colored, and 735 figures in the text Boston and New York, Houghton Mifflin Co 1910

This is the most ambitious work yet produced on the prehistoric implements of the United States The book deals almost wholly with this area, although Ontario and a few other sections of the Dominion of Canada are briefly covered Mexico and Central America with their highly developed stone age culture are omitted

The opening chapters deal with the classification of stone implements according to form and material, with quarry sites and methods of quarrying, the making of projectile points and knives, the cached deposits of finished and incomplete implements, and the general distribution of types Stone chipping in America had reached a high degree of excellence, and some of the finer examples from California, Tennessee and Ohio are probably not surpassed in workmanship by those of any section of the world

The author next describes what he calls the celt-hatchet-axe-adze class of implements which includes adze blades of various types and the grooved and grooveless axe They are shown in great variety The remainder of the first volume is devoted to problematical forms Under this general head are figured and described flat stone pendants, perforated tablets, winged ceremonials, "spud"-shaped objects of slate, pear-shaped pendants, discoidal stones, circular discs for paint, stone tubes, and other types Nearly nine hundred of these objects are illustrated from photographs furnished principally by collectors

The second volume opens with a chapter on bird stones and other effigies This is followed by a treatise on the tobacco pipe. Beginning with the early tubular type a large variety is shown ranging through the simple curved and angular forms to the platform and effigy pipes.

The next chapters are devoted to mortars, pestles, metates, mullers, stone dishes used in preparation of foods and paint, and to shell and bone ornaments, utensils, implements and weapons in considerable variety. The bone objects from the Mandan village sites are of special interest as are also the cut and inlaid bear teeth and engraved bones from the Ohio mounds

The native copper implements of the Great Lakes region are well illustrated. The elaborate ceremonial forms from the mounds of Ohio and other sections are of great interest Implements of this metal are principally knives and projectile points, perforated needles, fish hooks, adzes and axes. The ornaments are mainly beads, breast plates and ear buttons Some of the symbolic forms are elaborate, especially those shown in repoussé designs Various tribes in the United States had mastered the early stages of copper working, but they had not discovered the art of casting All the forms shown were made by hammering, annealing, grinding, perforating, cutting or embossing. Sheet mica was also cut into symbolic and ornamental designs similar to those of copper

A few textiles from the dry caves of Kentucky and the Ozark region and from the cliff-house ruins of Utah are described and illustrated The twined woven shoes from the Kentucky caves are unique The specimens shown in general however give but a faint idea of the great variety and beauty of the woven fabrics common among our Indians in early historic times.

The pottery of the United States is treated briefly, types from the various culture areas being shown. Many of the illustrations are from the publications of W. H. Holmes and C. B. Moore The author writes, "In the far north there is no pottery." He forgets the well-made pottery bowls, lamps and cooking pots of the Alaskan Eskimo.

The following chapters are devoted to grooved axes, celts, pendants and other forms in hematite, and also to miscellaneous objects of stone, such as salmon clubs from Oregon and Washington, perforated stone club heads, grooved stones for straightening and finishing arrow shafts, semi-lunar knives of slate, etc

The last two chapters are devoted to the author's conclusions which are grouped under several headings He acknowledges his indebtedness to forty individuals who contributed plates, figures, or to the text, or who allowed the use of published material. The most important of these original contributions is the excellent bibliography of forty-one pages by Dr Charles Peabody.

The "Stone Age in North America" is written primarily for collectors and the general public, but anthropologists will find much of interest in its pages.

The author's view point of American archeology is best shown by the following quotation from the opening chapter.

> It seems to me that the study of all these learned individuals, the results of which are set forth in the Indian "Handbook" [Bureau of American Ethnology], has led many of them to consider prehistoric life in America as nearly the same as the life of our Indians for the past one or two centuries. I can not believe that the arts of the past are the same to any appreciable extent as those which obtained at the time of the Lewis and Clark expedition

Again in the closing chapter, referring to certain New Jersey archeologists, he writes:

> They understand conditions as they existed in ancient times, and that is something that few men of to day grasp. It can not be learned from reading the reports, from studying in museums, or through obtaining a degree from one of our universities

The failure to comprehend the culture of the prehistoric American Indians except through the study of their stone implements and similar remains is a defect common to many archeologists which is usually apparent in their writings. We can never acquire a comprehensive knowledge of ancient American peoples without first studying existing tribes, and working backward through history, for stone implements alone can teach little without the knowledge thus acquired.

Charles C. Willoughby

A Concise History of Chemistry By T P HILDITCH. Pp 263, 12mo New York, D Van Nostrand Co 1911

This little treatise is an attempt to lay before students of chemistry a condensed summary of chemical history In many respects it is likely to be a useful book, although its conciseness is often an obstacle to intelligibility. Its use demands a rather wider range of knowledge than the average student is likely to possess The chapter upon the earlier history of chemistry, and the evolution of the science, covers familiar ground, but with much omission of detail, the chapters dealing with more specific subjects are very unequal in value The author is an organic chemist, and therefore the chapter upon organic chemistry is remarkably full and well handled It includes a number of tabular statements illustrating classes of compounds, which will doubtless be found valuable for reference The chapter on inorganic chemistry is much less satisfactory, and hardly up to date Apart from a brief reference to the use of the rare earths in incandescent lighting, there is little or nothing relative to the modern utilization of the less common metals, and the paragraph dealing with synthetic mineralogy is even misleading Physical chemistry receives rather better treatment, but even here the phase rule is given inadequate space and in the index it is credited to Wolcott Gibbs This error, which may be due to the indexer rather than to the author, is one of several indications that Mr. Hilditch is unfamiliar with American work. For example, Classen is credited with the introduction of electrolytic methods of chemical analysis, an advance which was really initiated by Wolcott Gibbs, and to which Edgar F. Smith has been a chief contributor So also, although Richards is barely mentioned on page 202, his name is omitted from the tabular statement of atomic weight methods which follows. In spite of these defects the volume may be serviceable to advanced students.

F. W. CLARKE

An Introduction to the Chemistry of Paints. By J. NEWTON FRIEND, Ph D, D.Sc New York, Longmans, Green & Co Pp 204, 8vo

This book is designed to present this subject to those who have had no training in physics or chemistry, and may be regarded as an unqualified success It makes no claim to be encyclopædic, and yet one finds terms and descriptions not given in much larger works

One or two errors have crept in, such for example as the saponification numbers (p. 126) being given as 19 3, etc, when they are ten times as large another is the position of the thermometer bulb in Fig 16 which is much too low

It is an excellent book and may be cordially recommended to all desiring information in this branch of technology

A. H GILL

THE WORK OF THE MARINE BIOLOGICAL STATION OF THE U S. BUREAU OF FISHERIES, AT BEAUFORT, N C, DURING THE YEAR 1910

A NUMBER of the investigations of the preceding year were continued and several new lines of work were begun The equipment of the laboratory was maintained and a number of additions were made to the same. A launch, operated by two gasoline engines, was substituted for the steam-launch formerly used The new launch is of small draft, which feature enables it to be used for dredging and for other operations in the vicinity of Beaufort. In addition to this vessel, the station has been equipped with a motor-boat, a sail-boat and twelve rowboats.

During July and August the laboratory was supplied as usual with electric lights. During the same period a mess was conducted at the station for the use of the scientific staff. The cost of table board for each member was five dollars per week, the same as during the preceding year. The laboratory was supplied with running fresh and salt water throughout the year. The small storage ca-

pacity of the salt-water tank has for several years made it necessary to pump water from the harbor at times when it was unsuited for experimental work. It is possible that a tank of 10,000 gallons capacity will be erected

The library was increased by the addition of a number of publications and by the receipt of reprints, the latter in many cases contributed by the authors

The work on the molluscan fauna, noted in the report for last year,[1] was continued The laboratory now has a nearly complete collection of the lamellibranchs of Beaufort correctly identified and labeled for study and reference The collection includes a number of species collected some distance off-shore by the Fisheries Steamer *Fish Hawk* The identifications were either made or verified by Dr. Wm H Dall, of the National Museum Some progress on the gastropods of the region was made along similar lines

The experimental work on the culture of the diamond-back terrapin was continued and considerable success was attained About 270 young terrapins were hatched during the season, and at the close of the year the whole stock was in a thriving condition A portion of the terrapins hatched during 1909 showed excellent growth during 1910 Preparations were begun to enlarge the scope of the work, which will include the construction of two additional concrete pounds These pounds will be of permanent service to the laboratory for numerous lines of scientific work, in case they can be spared for other than the original purposes As these pounds are supplied with fresh sea water at each high tide they would make excellent vivariums for keeping marine animals under nearly natural conditions, and they would at the same time be subject to control The terrapin work has been under the general direction of Professor W P. Hay, of Washington, D C.

In cooperation with the U S. Weather Bureau a daily record of the maximum and minimum temperatures and of the rain-fall, as well as of other miscellaneous meteorological phenomena, has been kept This work has been carried on without interruption since the summer of 1905 Some attention was given to the cultivation of the oyster in Pamlico and Core Sounds An inquiry was also made in regard to the character of fossil remains excavated during the process of construction of the new canal connecting Beaufort Harbor with the Neuse River

[1] SCIENCE, May 6, 1910

The facilities of the laboratory were utilized by a number of investigators, either for independent research or for the scientific work of the bureau They have kindly furnished abstracts of their work, which are included herewith

Professor H V Wilson, of the University of North Carolina, carried on an investigation for the bureau dealing especially with the regenerative power of the tissues in hydroids Professor Wilson had shown that when the tissues of certain sponges are forcibly broken up into their constituent cells, the cells will re-unite and form plasmodial masses which differentiate into perfect sponges It seemed desirable to learn whether this power was possessed by the tissues of other aquatic forms The investigation showed that hydroid tissues have this power

Experiments were conducted on two hydroids, *Pennaria tiarella* McCrady and *Eudendrium carneum* Clarke The phenomena were essentially the same in the two forms The cells and small cell masses into which the hydroid flesh is broken up reunite and form masses, the size of which is in a measure under control. These secrete a perisarc As compared with the corresponding masses in certain sponges they are subject to great mortality Some survive and after a few days give rise to hydranths with the characteristics of the species

The inquiry was extended to learn what power of fusion lies in the forcibly separated cells of the alcyonarian, *Leptogorgia*, and in those of the immature gonad in *Asterias*. In each case active fusion goes on between the cells and cell lumps into which the flesh has been broken up, and masses are obtained which acquire a smooth surface. These were

kept alive in laboratory dishes for some days, but underwent no further change

Dr E P Lyon and Mr L F Shackell, of St Louis University, worked upon problems connected with the fertilization of the ovum, directing their attention particularly to the chemical differences between fertilized and unfertilized eggs, using for the most part sea-urchin material

A large amount of material for chemical analysis was collected which is to be worked up in the Physiological Laboratory of St Louis University, also at Chicago through the cooperation of Professor Waldemar Koch, of the University of Chicago

Messrs Lyon and Shackell studied the changes in permeability occurring in eggs resulting from fertilization, and a preliminary article on this work was published in SCIENCE, August 19, 1910

Dr E W Gudger, professor of biology and geology, State Normal College, Greensboro, N C, spent ten weeks at the laboratory beginning May 25

Owing to the difficulty in getting eggs and embryos in May and early June, he was unable to complete his series for the life history of the gaff-topsail catfish He now lacks only the segmentation and the earliest invagination stages He was very successful, however, in hatching the eggs and rearing larvæ

He was also successful in getting about half the stages for the life history of the butterfly ray, and hopes to complete this series next season Some of these larvæ are very extraordinary in form.

In his work with the spotted sting ray, he was fortunate in obtaining three perfect specimens, two of them alive From these it is hoped that certain variations in color, spots and teeth may be explained

Careful photographic records were made of all the material referred to above, and an artist (Mr E A Morrison, Jr., of Baltimore), under a grant from the Carnegie Institution, spent two weeks making drawings, chiefly of early stages of the gaff-topsail catfish

Dr. H. S Davis, of the University of Florida, worked at the laboratory during portions of July and August The time was spent in examining fishes for parasitic protozoa and in observations on the morphology and life history of the parasites found, the work being largely of a preliminary nature to serve as a basis for further more detailed investigations

A total of 26 species of fishes were examined for protozoan parasites In the case of several of the more common species many individuals were examined, but with the rarer species the investigation was often necessarily limited to the examination of one or two specimens Most of the parasites found were Myxosporidia, and of the 26 species of fish examined 14 were found to be infected with these parasites As is usually the case, the gall-bladder was found to be most commonly infected, 13 out of the 14 species showing infection of this organ In 2 species both the gall- and urinary-bladders were infected, but, of course, by different species of Myxosporidia. In a few cases the gall-bladder was found to be simultaneously infected with 2 species of Myxosporidia. In most cases the percentage of infected individuals was high, sometimes reaching 100 per cent This was found to be especially true of the adults which were much more commonly infected than the young of the same species. It is significant that, in the case of those species in which Myxosporidia were not found, usually only one or two individuals were available for examination and these were often immature

In the case of all the species of fish found to be infected no myxosporidian parasites have previously been recorded

The Myxosporidia found belong to 6 genera, as follows, the species in many cases being apparently undescribed *Sphærospora, Sphæromyxa, Chloromyxum, Ceratomyxa, Myxobolus* and *Henneguya* In several cases, on account of the absence of material in the proper stages, it was found impossible to determine the genus

In at least two cases the same species of Myxosporidia was found to occur in two or more species of fish

A large amount of material was preserved with a view of working out the life history of several species as far as possible, and is being worked up as rapidly as time will permit.

The fresh blood of a large number of individuals was carefully examined for trypanosomes or Hemosporidia, but with uniformly negative results

Dr. James J. Wolfe, professor of biology, Trinity College, Durham, N C, spent the months of July and August at the laboratory Dr Wolfe collected material and began studies with a view to publishing a complete life history of *Padina* The microscopic technique was worked out and a beginning made on the cytological side of the problem In addition sixty-six cultures consisting of germinating tetraspores, fertilized and unfertilized eggs, were started in the laboratory on oyster shells and later transferred to the harbor for the purpose of testing by cultural methods the theory of alternation of generation and also the vitality of eggs which germinate parthenogenetically. The cultures which survived were collected and forwarded to Dr Wolfe for examination later in the season Contrary to published notices, female plants were found here in abundance. These bear a close resemblance to tetrasporic individuals—a fact which probably accounts for their having been overlooked Contrary also to published notices, it was found rather late in the season that there is a regular succession or periodicity in the production of the sexual elements.

Dr. H. S. Colton, of the University of Pennsylvania, worked at the laboratory during the spring. During the previous winter at the University of Pennsylvania, Dr. Colton had been working on the morphology and physiology of the pyloric gland of the ascidian, *Botryllus*. This organ is composed of branching tubules with blind endings. These tubules ramify over the walls of the intestine, opening by means of a single duct into the stomach. This gland he has found to have the characters of an excretory organ in *Botryllus*.

While at Beaufort last spring, he was able to extend these observations on to other forms of Tunicates—*Amaroucium, Perophora, Ascidia, Styela* and *Molgula* The result of those observations helped confirm the conclusion arrived at by the study of the organ in *Botryllus*

Dr J M Wilson, of Washington, D C., made collections and preparations of selachian brains for the purpose of comparison with the teleostean brain, especially that of *Ameiurus*

Mr. W H Kibler, of Guilford College, collected material for the study of the origin of the sex cells of fishes. Consecutive stages in the development of the toadfish were obtained, together with certain stages from the blenny and *Fundulus*.

Mr L. F Shackell, instructor in physiology, St Louis University School of Medicine (in addition to his collaborative work with Dr. Lyon), collected considerable material for a study of the nutritive value of the edible crab, *Callinectes sapidus* A study is also being made on the chemical changes taking place in *Callinectes* during the moulting period. Most of the analyses are being made in St Louis

Mr Peter Okkelberg, of the University of Michigan, studied principally fishes and fish parasites. Most fishes were found to be infested with parasites and collections were made for future study.

A general study was also made of the local fauna Note was taken of the distribution and habits of the different forms, with special reference to their adaptation to environment. Ample opportunity was furnished for the study of live animals under control. The structure and development of many forms were also studied.

Protozoans, jellyfish and larvæ of different kinds were obtained by towing, and a study was made of the material brought up by the dredge in various parts of the harbor. The extensive shoals and beaches were frequently surveyed and all the material found was studied as far as time permitted.

Mr. Raymond Binford, Johns Hopkins University, continued the study of the life histories of the crabs of Beaufort, especially that of *Menippe mercenaria* By a later study of the material killed and preserved during the summer, the processes of fertilization and gastrulation in this crab are being worked out.

In experiments in which eggs were subjected to differences of temperature, those which were kept a few degrees above normal hatched nine days after they were fertilized, while those kept below the normal hatched on the thirteenth day after fertilization

Some twelve hundred of these crabs were caught in the waters about the Beaufort harbor during the summer

Mr J D Ives, instructor in biology, Wake Forest College, made observations on the regeneration of nemerteans and *Amphitrite* during the month of August Sections of nemerteans were found to regenerate readily The anterior surfaces of the sections were found to regenerate but a small amount of new material compared with that formed by the posterior surfaces The posterior surfaces of the sections regenerated rapidly In about four weeks, sections of worms not over one half inch long were found to more than double their length with new material

The tentacles of *Amphitrite* when pulled off were found to regenerate readily In about ten days or two weeks after removal, the tentacles attained nearly an inch or about half of their normal length When the entire tentacle bearing somite is cut off, the worm lives almost as well as when only the tentacles are removed When the somites bearing both the tentacles and the first pair of branchiæ were cut off, some few specimens lived for over two weeks.

HENRY D ALLER

THE BIOLOGICAL EFFECTS OF RADIUM[1]

AMONG the first discoveries made after the production of concentrated radium salts was that radium is capable of causing intense effects upon living tissues. We were not unprepared for such a discovery in the case of radium because similar phenomena had been observed early in the study of X-rays. In the case of X-rays the discovery had been totally, and very unfortunately, unexpected The early burns from radium were of the same character as X-ray burns, and later detailed study has shown that the effects upon tissues of the two agents are practically identical An appreciation of this fact is useful at the outset of a consideration of the biological effects of radium, it gives one at once a large number of analogous facts that have been well studied and, because of the more extensive study that has been made of the biological effects of X-rays, enables one to correlate more satisfactorily some of the isolated observations upon the actions of radium Because the gross effects of radium, which furnish us many valuable facts, can be studed in the skin, and because the effects upon the various tissues of the skin give us the most comprehensive view of the biological effects in general of radium, it is conducive to clearness to consider first the effects of radium upon the skin, meaning by the skin in this connection the human skin or skin of similar structure of other animals

When the human skin is exposed for a sufficient length of time to an active radium salt a peculiar and definite reaction is set up, of which the first striking feature is that it does not develop until after a relatively long period of quiescence—as a rule about two weeks In a skin containing a considerable amount of pigment, there is first an increase of pigment, shown by an ordinary "tanning" of the exposed surfaces. If there are any freckles or pigmented spots in the exposed area, these become darker. Along with this pigment stimulation there occurs a reddening of the skin, with a feeling of irritation and burning such as one has from sunburn. The reaction may stop at this point and after a few days gradually subside, the redness and irritation diminish, there is some scaling from the surface and in a few days more no evidence of the reaction remains,

[1] Address before the Illinois State Academy of Science, Chicago, February 18, 1911

except the increased pigmentation which is very slow to disappear.

In this reaction we have had simply the familiar picture of sunburn. But the process, in many cases, goes much further, and then there occurs a reaction which is peculiar to X-rays and radium. After the development of an inflamed, reddened area of skin the surface becomes intensely congested, purplish, and then blisters form. At the same time, or before, the hairs loosen and fall out. Next the blisters rupture and leave a surface covered by a necrotic pellicle, like a diphtheria membrane. And the reaction may go still further, with the formation of an ulcer whose striking characteristics are its painfulness and its extreme indolence, showing, it may be for months, no tendency to regeneration. The process may stop at any of the stages described above. If subsidence occurs short of ulceration the skin may again become normal, but after the severe reactions without ulceration, and after ulceration when healing takes place there may be very distinct permanent changes in the skin. The hairs grow sparsely or not at all; the pores are very fine or absent, from destruction of the glands of the skin. The skin is thinned, with here and there roughened horny points or patches up to the size of a finger nail, and the surface is reddened from numerous dilated capillaries which show through the thinned horny epidermis.

We have here, as a result of these powerful forms of radiant energy, a picture of extreme interest. The condition is in fact an exact, sometimes an exaggerated, picture of the atrophic senile skin, with its dilated blood vessels and senile keratoses. As a matter of fact the picture is so nearly that of senile skin that I was able, in the case of X-ray lesions, to predict that cancers of the skin would be found to develop in them because the keratoses of old age are so frequently the starting point of cancers. It would take us too far from our subject to give all of the reasons for the idea, but the identity of chronic radium and X-ray changes in the skin with those of the senile skin, strongly indicate that the senile changes of the skin are in good part the result of the less powerful action over a long period of years of sunlight. Another fact, that is beside our topic, is highly interesting in this connection. Cancers develop in the keratoses of X-ray and radium dermatitis, and in them we have one form of carcinoma which is directly traceable to its exciting cause, and only by bringing in a *deus ex machina* in the form of later infection can one avoid the conclusions that at least in these lesions we have cancer which is not of microbic origin.

When radium is applied to various pathological lesions in the skin the same phenomena occur that are seen in healthy skin, with the addition that under proper precautions selective destructive effects may be produced upon the diseased tissues. Take, for illustration, nodules of tuberculosis or of carcinoma or sarcoma (cancers) in the skin. With proper care in grading the applications a reaction may be produced which will cause these tissues to be entirely destroyed, while this reaction is not sufficient to destroy the normal stroma in which they are situated, or, if it does destroy the normal tissues in the involved area, they will regenerate with the formation of healthy scars. It is also found in itching and painful conditions of the skin that the applications have a definite anesthetic effect.

The microscopic changes in tissues undergoing a radium reaction are even more interesting than the gross changes. In the early stages of radium irritation sections show evidences of proliferation of the tissue elements, such as indicate an over-stimulation of the cells by a peculiar irritant. These changes are most marked in the tissues of the greatest functional activity. At first there are an increased production of pigment, and an exaggerated proliferation of the germinal and younger (deeper) cells of the epidermis, especially of the cells of the follicles of the epidermis, in the corium or body of the skin, there are dilatation of the capillaries, an infiltration of round cells, and œdema—the changes of inflammation. Later the changes become exaggerated: there is proliferation of the inner layer of the blood vessels (an ob-

literating endarteritis), the round-cell infiltration becomes intense, the connective tissue fibers are œdematous and stain poorly In the epidermis the cells show extreme degenerative changes, they become vacuolated, the nuclei are fragmented, there is degeneration of the cytoplasm so that stains are taken poorly, and complete breaking down of many cells. These changes are especially intense in the highly specialized and active cells of the appendages of the skin—the hair follicles and the sweat and sebaceous glands—and they may result in the obliteration of these structures, a phenomenon which, occurring as it may without destruction of the surrounding tissues, is not produced by any other known agent In the last stage in a radium reaction there is necrosis of all of the affected tissues, the connective tissue stroma being the most resistant and last to break down In diseased tissue of the skin such as epithelioma (cancer) and lupus (tuberculosis), there is the same sort of reaction, it is also found that the pathological tissues which are composed of growing cells, often of embryonic type react in the same way as the active sensitive tissues of the normal skin. They are more sensitive to the effects than the stroma in which they are growing, disintegrate or degenerate readily, and are destroyed before or without destruction of the connective tissue around them

It is evident in this process that we are dealing with an agent whose results are produced by influencing the biological processes of the cells themselves The effects are not produced by an immediate destructive action of the rays, as a heat burn, for example, is produced There is no immediate effect from the application of radium, it is only after days, it may be two or three weeks, that the effects appear The inference is that the radiations set up some process in the tissues which itself ends in their destruction. The whole process is one of exaggerated stimulation of the activity of the cells of the tissues a stimulation which varies in degrees with the degree of specialization or functional activity of the different type of cells In its slightest degrees it is the ordinary protective process that occurs under exposure to sunlight, but under the unusual and extreme irritation of this artificial form of radiant energy the reaction becomes destructive

Since the effects of radium have had therapeutic application, it may be interesting to pause to consider briefly this aspect of the subject

As I have suggested, the effects of radium to a degree are selective in that they excite the intensest reaction in the cells of great functional activity whether this be in the exercise of a special function or the simpler function of growth Thus there is produced by radium (1) A stimulation of the cells, (2) an exaggerated effect upon the highly specialized structures of the epidermis, viz, the hair follicles, and the sebaceous and sweat glands, and likewise upon the basal or germinal layer, (3) an endarteritis or proliferation of the lining membrane of the blood vessels which may lead to obliteration of many blood vessels, (4) destruction of masses of diseased tissues, which are composed of young growing cells or immature cells

These effects upon tissues suggest the possible use of radium for various therapeutic purposes, as follows (1) To stimulate chronic processes This principle has been successfully used in the treatment of some chronic inflammatory processes in the skin (2) To destroy or diminish the follicles of the skin, particularly the hair follicles This principle has had practical application with X-rays, but because of the small quantities available, not with radium, except in the case of hairy nævi (birthmarks) (3) To obliterate blood vessels in the skin This has had practical application, with very successful results, in the treatment of vascular nævi (birthmarks) (4) To destroy pathological tissues This use is of course possible of wide application, and has been successful in various diseases of the skin and the adjacent underlying structure, especially in carcinomas and sarcomas (cancers) Its limitation in cancer is that it is only effective upon such

lesions as can be directly exposed. As the action is to a degree selective, radium and X-rays have had very valuable practical uses in these diseases. (5) Finally the anodyne effect of radium has had some application in the relief of itching and of pain.

The therapeutic uses of radium are obtained from the above indications. The indications which might seem to be derived from the effect upon other organisms, especially upon bacteria, yet to be considered, have not increased the practical application of the agent.

Experiments upon other mammals have added little to the facts given above. Experiments on rabbits have shown that exposure to the radiations causes anesthesia in peripheral nerves (Beck), confirming a fact established by clinical experience. Danysz and Bohn have shown that the nervous system of certain young animals is peculiarly sensitive to the effects of radium, exposures so arranged as to reach strongly the cerebrospinal axis causing paresis, ataxia, convulsions and death. These phenomena, with negative controls, were elicited in mice, which proved most sensitive, and in guinea pigs and rabbits. The sensibility is very much greater in the very young animals, persists in older mice, but disappears in great degree in adult guinea pigs and rabbits. Similar effects upon the nervous system of man from either radium or X-rays do not occur.

I can not take more than enough time to refer very briefly to the effects of radium upon micro-organisms, upon development and upon plants. The knowledge upon these subjects has been carefully summarized in a paper by Hussakof, of Columbia University, which is readily available.

Several experiments have shown the inhibitive or, under stronger exposures, destructive, effect of radium rays upon various bacteria in cultures—the bacillus prodigiosus, colon bacillus, typhoid bacillus, anthrax bacillus and the spirillum of cholera. These are the only biological findings differing from those with X-rays, and are probably due to the greater superficial effect of the alpha and beta rays because of their very slight penetration as compared with the softest X-rays. They indicate a close similarity, with a difference chiefly in degree, in their biological effects between alpha and soft beta rays and ultra-violet rays.

Similar results have been obtained by several observers from exposures of numerous forms of protozoa. Their growth is at first stimulated, then inhibited, and after intense exposures they are destroyed.

Experiments on various eggs, embryos and larvæ have shown, as would be expected, in these embryonic tissues, a high degree of susceptibility. Growth is retarded, monstrosities develop, and, from prolonged exposure, death occurs.

In plants the results of experiments may be summarized briefly as first stimulation of growth, and under stronger application, retardation or complete inhibition of growth.

This consideration has been directed to the effects of radium rays. As to the emanations, it may be stated briefly that experiments with the emanations upon young mice, upon bacteria, and upon protozoa show results quite like those from exposure to the rays.

There is apparently no difference in kind in the effects upon tissues between the different radium rays. Alpha rays have so little penetration that their effect is expended entirely upon the most superficial tissues, but when they are screened out the only difference in the reaction is one of intensity and depth. Exner, in a repeated experiment, by deflecting the beta rays with an electro-magnet directed them upon one white mouse while the gamma rays fell upon another mouse equidistant from the radium. Fifteen days after exposure, which had been for 18¾ hours, a similar ulceration appeared on the tails—the exposed areas—in both mice. All three forms of radium rays then, are physiologically active. This fact might fairly be inferred from their actinic properties. For the physiological effects of all forms of radiant energy, there seems every reason to

believe, are a manifestation of the same actinic effects that we have long been familiar with in certain inorganic substances Indeed, beginning with the red rays of light at one end of the scale and ending with the hardest X-rays and gamma rays at the other, we find physiological effects differing chiefly in degree and corresponding in intensity with the actinic strength of the respective rays

What the bio-chemical processes are that are set going by radium, or by the more familiar forms of actinic energy, we are in no position to say From experiments with radium upon eggs Schwartz proposed that all of the effects of radium upon tissues were due to decomposition of lecithin Hussakof suggests from experiments of Willcock, Zuelzer and Kornicke that oxygen in some not understood way seems to play a part in the process There is every reason to believe that the process is not explicable by any simple chemical reaction Radium rays do not produce an immediate effect upon living tissues, similar to the reduction of silver salts, for example They have an effect upon the life processes of the cells, and these after a relatively long time produce the results that we recognize as a radium reaction In other words the process is a vital process, and one, doubtless, involving all of the chemical complexity of cell life itself

ON THE CLASSIFICATION OF SAND GRAINS

PROFESSOR W H SHERZER has just published an important paper containing a classification of sands[1] in which a successful attempt is made to use origin as the primary factor for determining subdivisions I say successful, because I believe Sherzer's classification to be a sound one for the reason that it is a natural one In detail, as he himself says, it requires further amplification, but I believe that its leading features will stand. He distinguishes the following types (1) *Glacial sand type*, (2) *volcanic sand type*, (3) *residual sand type*, (4) *aqueous sand type*, (5) *æolian sand type*, (7) *organic sand type*, (8) *concentration sand type* The first five of these are clastic, the others are non-clastic To the clastic he might have added as number 6 the artificially produced sands (or mechanico-organic) which no classification can afford to neglect, and to the non-clastic might be added, for completeness sake, (9) the granular snow and the firn or nevé, precipitated from the atmosphere, and (10) lapilli of igneous origin, but not pyroclastic With the glacial sand group (1) Sherzer compares those formed by avalanches and rock slides, by rock and mud flows, and by earth movements along joint planes, *i. e*, the familiar fault sand He also adds the sand produced in the manufacture of talus, but this, when not due to mechanical slipping, clearly belongs under his residual type

As thus included, the mechanical abrasion sands glacial, fault, etc, come under the heading of *autoclastic sands*, and the series given by Sherzer, with the addition of the artificial sands, corresponds exactly to subdivisions of clastic rocks which I published in 1904,[2] as shown in the following table, where the corresponding divisions of my

[1] W H Sherzer, "Criteria for the Recognition of the Various Types of Sandgrains," *Bull. Geol Soc America*, Vol. 21, No. 4, pp. 625–662, pls. 43–47.

[2] A. W. Grabau, "On the Classification of Sedimentary Rocks," *American Geologist*, Vol. 33, pp. 228–247, April, 1904

classification are numbered to agree with Sherzer's types. The technical terms for the mechanical types of the second column make for uniformity as well as euphony, while lending themselves readily to compounding

A CLASTIC SANDS

(Exogenetic)

Sherzer's Types of Sands

1 Glacial, etc, sand
2 Volcanic sand
3 Residual sand
4 Aqueous sand
5 Æolian sand
6 (Artificial sand) added

Corresponding Divisions in Grabau's Classification

1 Autoclastic sand or *autoarenyte*
2 Pyroclastic sand or *pyrarenyte*
3 Atmoclastic sand or *atmoarenyte*
4 Hydroclastic sand or *hydrarenyte*
5 Anemoclastic sand or *anemoarenyte*
6 Bioclastic sand or *bioarenyte*

B NON CLASTIC SANDS

(Endogenetic)

Sherzer's Types of Sands

7 Organic sand
8 Concentration sand
9 (Snow and firn sand) added
10 (Lapilli or igneous sand) added

Corresponding Divisions in Grabau's Classification

7 Biogenic sand [a]
8 Hydrogenic sand [a]
9 Atmogenic sand [a]
10 Pyrogenic sand [a]

In my classification of sedimentary rocks, I pointed out that after the determination of the agent, the further subdivision of clastic rocks must be on the basis of texture, and that three textures are to be recognized as of primary importance, namely, (1) *rudaceous texture*, the texture of rubble or material coarser than sand (*i e.*, approximately above 2 to 2 5 mm), (2) *arenaceous texture* or the texture of sand (2 5 to 05 mm) and (3) *lutaceous texture* or the texture of mud, *i e*, rock flour, clay, etc These three types of texture produce rocks, consolidated or unconsolidated, which may be classified as *rudytes*, *arenytes* and *lutytes*, respectively. Rudytes and lutytes are found in each of the divisions in which arenytes are found; we have *autorudytes* and *autolutytes*, *hydrorudytes*, *hydrolutytes* and all the rest, just as we have the various arenytes given above Sherzer too is fully of the opinion that the coarser- and finer-than sand particles should be classified on the same basis as the sand itself

[a] These are not arenytes in the sense used above—*i e*, for clastics only

Non-clastic, granular material constitutes sands, etc, only in the broader or popular sense of the term, while it is quite proper to speak of organic or chemical sands, it is desirable that the technical terms arenyte, lutyte, etc, be restricted to clastic rocks only

Professor Sherzer further subdivides his types on the basis of reworking by some other agent Thus he has an aquoo-residual type in which grains originally of residual (atmoclastic) origin are reworked by water. On the other hand, a residuo-aqueous type is one in which original aqueous sands (hydroclastic) have become weathered under the influence of the atmosphere These two subtypes may be termed, respectively, the *hydro-atmoclastic* and the *atmohydroclastic* subtypes of sands. In like manner the other combinations may occur and we may have *anemohydro-*, atmo- and autoclastic sands, *hydro-anemo-*, atmo-, pyro- and autoclastic sands, *anemo-atmo-*, hydro-, pyro- and autoclastic sands, terms which have at least the advantage of euphony over the English equivalents, such as æolo-aqueous or residuo-æolian But the selection of terms is a minor matter, the important thing being the correct classification on a genetic basis, and this Professor Sherzer has done for sands I am happy to find myself so fully in accord with him, and that in the endeavor to classify materials he has come to substantially the same results that I have reached in approaching the matter from the more theoretical basis of principles of classification

It may perhaps be questioned if the secondarily enlarged æolian sand grains which Professor Sherzer claims as concentro-æolian should be included in this classification, which is essentially one of the material in its orig-
